## 1. Summary: what is this living guideline?

**Clinical question:** What is the role of drugs in the treatment of patients with COVID-19?

**Target audience:** The target audience is clinicians and health care decision-makers.

**Current practice:** The evidence base for therapeutics for COVID-19 is increasing rapidly, and some treatments of proven benefit have emerged. Numerous randomized trials of many drugs are underway to further inform practice. This version of the WHO living guideline contains new recommendations on a combination of neutralizing monoclonal antibodies (casirivimab and imdevimab) based on four randomized controlled trials (RCTs).

**Recommendations:** In this update, the panel makes a conditional recommendation to use casirivimab and imdevimab in non-severe patients, the condition being patients' risk of severe disease: patients at highest risk represent good candidates for use of the intervention. The panel also makes a conditional recommendation to use casirivimab and imdevimab in patients with severe and critical infection, the condition being seronegative status.

Previous recommendations include:

- a strong recommendation for systemic corticosteroids in patients with severe and critical COVID-19;
- a strong recommendation for IL-6 receptor blockers (tocilizumab or sarilumab) in patients with severe and critical COVID-19;
- a conditional recommendation against systemic corticosteroids in patients with non-severe COVID-19;
- a conditional recommendation against remdesivir in hospitalized patients with COVID-19;
- a strong recommendation against hydroxychloroquine in patients with COVID-19 of any severity;
- a strong recommendation against lopinavir/ritonavir in patients with COVID-19 of any severity;
- a recommendation against ivermectin in patients with COVID-19 of any severity, except in the context of a clinical trial.

**How this guideline was created:** A Guideline Development Group (GDG) of content experts, clinicians, patients, ethicists, and methodologists produced recommendations following standards for trustworthy guideline development using the Grading of Recommendations Assessment, Development, and Evaluation (GRADE) approach. No conflict of interest was identified for any panel member or other contributors to the guideline development process. This living guideline represents an innovation from the World Health Organization (WHO), driven by the urgent need for global collaboration to provide trustworthy and evolving COVID-19 guidance informing policy and practice worldwide. WHO has partnered with the non-profit MAGIC Evidence Ecosystem Foundation (MAGIC) for methodologic support and development, and dissemination of living guidance for COVID-19 drugs to prevent (1) and treat COVID-19 (2). These guidelines are also published in the BMJ (3)(4), supported by a living systematic review with network meta-analysis (LNMA) that informs the recommendations (5)(6)(7)(8).

**The latest evidence:** The GDG's recommendations for casirivimab and imdevimab were informed by results from the LNMA that pooled data from four RCTs with 4722 patients with non-severe disease (9)(10), and one RCT (RECOVERY) with 9785 patients with severe or critical disease that included a crucial subgroup analysis examining effect modification associated with serological status (seropositive versus seronegative) (11).

In non-severe patients, the pooled data from 3432 patients in two RCTs showed, because of very low baseline risk, trivial or no effects of the intervention on mortality or need for mechanical ventilation (moderate certainty evidence). In 4722 non-severe patients in four RCTs, casirivimab and imdevimab likely reduce need for hospitalization (moderate certainty evidence; odds ratio [OR] 0.29; 95% confidence interval [CI]: 0.17–0.48; absolute effect estimate using the baseline risk in the trials of 29 fewer hospitalizations per 1000 patients; 95% CI: 35 fewer to 21 fewer). The absolute benefit will be appreciably greater in those at highest risk for hospitalization and much lower for those at low risk (the majority of the population with non-severe illness).

In the overall population of patients with severe and critical COVID-19, casirivimab and imdevimab may not have an impact on mortality (low certainty evidence; OR 0.94; 95% CI: 0.86–1.03; absolute effect estimate 8 fewer per 1000 patients; 95% CI: 18 fewer to 4 more). Evidence was of low certainty because of imprecision and high likelihood that casirivimab and imdevimab have, in the seronegative and seropositive patients included in the overall group, very different effects. In this population the evidence regarding the impact of the intervention on need for mechanical ventilation and duration of hospitalization was very low certainty.

A credible subgroup effect demonstrates that casirivimab and imdevimab likely reduce mortality in patients who are seronegative (moderate certainty evidence; RR 0.85; 95% CI: 0.76–0.95; for severe patients absolute effect estimate 39 fewer per 1000; 95% CI: 62 fewer to 13 fewer; for critical patients absolute effect estimate 69 fewer per 1000; 95% CI: 110 fewer to 23 fewer). In the seronegative patients, the intervention possibly reduces the need for mechanical ventilation (moderate certainty evidence; RR 0.87; 95% CI: 0.77–0.98; absolute effect estimate 42 fewer per 1000; 95% CI: 74 fewer to 6 fewer). Aside from the credible subgroup effect, the GDG found no evidence of subgroup effects on age or time from onset of illness in the non-severe, or on age, time from onset of illness, and severity in the severe and critically ill.

**Understanding the recommendations:** When moving from evidence to recommendations to use casirivimab and imdevimab in non-severe patients, the GDG recognized the limited availability, in relation to the number of eligible patients, of casirivimab and imdevimab and the very small benefits in reducing hospitalization that low-risk patients would achieve with use of the intervention. Thus the conditional recommendation reflects the GDG's view that drug administration be reserved for those at high risk. Although there is no established decision tool to definitively identify those at high risk of hospitalization, evidence exists that factors substantially increasing risk include no prior vaccination, older age, immunosuppression, and presence of chronic conditions.

In patients with severe or critical illness, the conditional recommendation in favour of casirivimab and imdevimab use reflects the likelihood that any benefits are restricted to patients who are seronegative. This implies rapid identification of serological status at the time of presentation of severe or critical illness to guide use in this population. Several rapid, relatively inexpensive tests are available with adequate performance characteristics that could be used to identify patients who are seronegative and likely to benefit from casirivimab and imdevimab administration.

#### Info Box

This WHO *Therapeutics and COVID-19: living guideline* now includes two recommendations regarding the combination of neutralizing monoclonal antibodies, casirivimab and imdevimab: a conditional recommendation in favour of use in non-severe patients (the condition being patients' risk of severe disease: patients at highest risk represent good candidates for use of the intervention); and a conditional recommendation in favour of use in the severe and critically ill (the condition being seronegative status).

The section text provides an executive summary of the guidance. The [first version](#) of the living WHO guideline, published 2 September 2020, provides recommendations for corticosteroids; the [second version](#), published 20 November 2020, provides recommendations on remdesivir; the [third version](#), published 17 December 2020, provides recommendations on hydroxychloroquine and lopinavir/ritonavir; the [fourth version](#), published 31 March 2021, provides recommendations on ivermectin; and the [fifth version](#), published 6 July 2021, provides recommendations on IL-6 receptor blockers (2). This update does not include changes to the recommendations for any of these other drugs.

This living guideline will incorporate new recommendations on other therapies for COVID-19 and updates on existing recommendations. The guideline is therefore written, disseminated, and updated here in MAGICapp, with a user-friendly format and easy to navigate structure that accommodates dynamically updated evidence and recommendations, focusing on what is new while keeping existing recommendations within the guideline.

Please visit the [WHO website](#) for the latest version of the guidance (2), also available in the BMJ as [Rapid Recommendations](#) (4), together with the [living network meta-analysis \(LNMA\)](#) (5)(7)(6), a major evidence source for the guidelines.

Guidelines with recommendations on prophylaxis against COVID-19 have been published separately (3), and the WHO *COVID-19 Clinical management: living guidance* can also be found separately (12).

## 2. Abbreviations

ALT	alanine aminotransferase
ARDS	acute respiratory distress syndrome
CAP	community-acquired pneumonia
CI	confidence interval
COVID-19	coronavirus disease 2019
DOI	declaration of interests
eGFR	estimated glomerular filtration rate
GDG	guideline development group
GI	gastrointestinal
GRADE	Grading of Recommendations Assessment, Development and Evaluation
GRC	guideline review committee
IL-6	interleukin-6
IMV	invasive mechanical ventilation
LNMA	living network meta-analysis
MAGIC	Magic Evidence Ecosystem Foundation
MD	mean difference
NMA	network meta-analysis
OIS	optimal information size
OR	odds ratio
PICO	population, intervention, comparator, outcome
PMA	prospective meta-analysis
RCT	randomized controlled trial
RR	relative risk/risk ratio
SAE	serious adverse event
WHO	World Health Organization

### 3. Background

As of 2 September 2021, over 218 million people worldwide have been diagnosed with COVID-19, according to the WHO dashboard (13). The pandemic has thus far claimed more than 4.3 million lives (13). Vaccination is having a substantial impact on case numbers and hospitalizations in a number of high-income countries, but limitations in global access to vaccines mean that many populations remain vulnerable (13)(14). Even in vaccinated individuals, uncertainties remain about duration of protection and efficacy of current vaccines against emerging SARS-CoV-2 variants.

Taken together, there remains a need for more effective treatments for COVID-19. The COVID-19 pandemic – and the explosion of both research and misinformation – has highlighted the need for trustworthy, accessible and regularly updated living guidance to place emerging findings into context and provide clear recommendations for clinical practice (15).

This living guideline responds to emerging evidence from RCTs on existing and new drug treatments for COVID-19. More than 4200 trials investigating interventions for COVID-19 have been registered or are ongoing (see section on emerging evidence) (16). Among these are large national and international platform trials (such as RECOVERY, WHO SOLIDARITY, REMAP-CAP and ACTIV) that recruit large numbers of patients in many countries, with a pragmatic and adaptive design (17)(18)(19)(20). These platform trials are currently investigating and reporting on numerous interventions, including antiviral monoclonal antibodies and immunomodulators. This rapidly evolving evidence landscape requires trustworthy interpretation and expeditious clinical practice guidelines to inform clinicians and health care decision-makers.

#### 3.1 What triggered this version of the guideline?

This sixth version of the WHO living guideline addresses the use of casirivimab and imdevimab in two groups of patients: those with non-severe COVID-19, and those with severe and critical illness. It follows the availability of pre-prints of four trials, that are part of the larger adaptive randomised master protocol addressing patients with non-severe illness, and of the RECOVERY trial addressing severe and critically ill patients (9)(10)(11).

Casirivimab and imdevimab are two distinct neutralizing monoclonal antibodies to the SARS-CoV-2 virus, and thus have a plausible mechanism of action for beneficial impact on COVID-19 illness.

#### 3.2 Who made this guideline?

For the casirivimab and imdevimab recommendations, WHO convened a Guideline Development Group with 40 individuals, of whom 36 were content experts (clinicians, methodologists, scientists) and four were patients who previously had COVID-19. The methods chair (methodological expertise) and a clinical chair (content expertise) guided the GDG discussions.

WHO selected GDG members to ensure global geographical representation, gender balance, and appropriate technical and clinical expertise. The technical unit collected and managed declarations of interests (DOIs) and found no GDG member to have a conflict of interest. In addition to distribution of a DOI form, during the meeting, the WHO Secretariat described the DOI process and an opportunity was given to GDG members to declare any interests not provided in written form. Web searches also did not identify any conflicts. The [MAGIC Evidence Ecosystem Foundation](#) provided methodological experts with high-level expertise in standards and methods for systematic reviews and guideline development, including GRADE. These experts helped to support each of the recommendations. In addition, MAGIC offered innovations in processes ([BMJ Rapid Recommendations](#)) and platforms ([MAGICapp](#)) for developing living guidance in user-friendly formats. The methodological experts were not involved in the formulation of recommendations. MAGIC also worked with the BMJ to coordinate the simultaneous scientific publication of the living WHO guidelines (4).

#### 3.3 How to access and use this guideline

This is a living guideline from WHO. The recommendations included here will be updated, and new recommendations will be added for other drugs for COVID-19.

The guideline is written, disseminated and updated in MAGICapp, with a format and structure that ensures user-friendliness and ease of navigation (22). It accommodates dynamic updating of evidence and recommendations that can focus on what is new while keeping existing recommendations, as appropriate, within the guideline. Section 4 outlines key methodological aspects of the living guideline process. In addition, the methodologic support team, under the coordination of the Guideline Collaboration Committee (see Section 9), worked with the BMJ to develop the presentation, communication and coordinate the simultaneous scientific

publication of the living WHO guidelines (4).

The guideline is available via:

- [WHO website in PDF format](#) (2)
- [MAGICapp in online, multilayered formats](#)
- [WHO Academy app](#)
- [BMJ Rapid Recommendations](#) (4)

The purpose of the online formats and additional tools, such as the infographics, is to make it easier to navigate and make use of the guideline in busy clinical practice. The online multilayered formats are designed to allow end-users to find recommendations first and then drill down to find supporting evidence and other information pertinent to applying the recommendations in practice, including tools for shared decision-making ([clinical encounter decision aids](#)) (22).

Additional educational modules and implementation tools for health workers can be found via:

- [WHO COVID-19 essential supplies forecasting tool \(COVID-ESFT\)](#)
- [WHO Clinical care for severe acute respiratory infection toolkit: COVID-19 adaptation](#)
- [WHO Openwho.org clinical management course series](#)
- [WHO Academy app](#)

This living guideline from WHO is also used to inform the activities of the [WHO Prequalification of Medicinal Products](#).

## 4. Methods: how this guideline was created

This living WHO guideline was developed according to standards and methods for trustworthy guidelines, making use of an innovative process to achieve efficiency in dynamic updating of recommendations (2). The methods are aligned with the [WHO Handbook for guideline development](#) and according to a pre-approved protocol (planning proposal) by the Guideline Review Committee (GRC) (23).

### Related guidelines

This living WHO guideline for COVID-19 treatments is related to the larger, more comprehensive guidance for [COVID-19 Clinical management: living guidance](#), which has a wider scope of content and has been regularly updated (12). The first five versions of this WHO [Therapeutics and COVID-19: living guideline](#), addressing corticosteroids, remdesivir, hydroxychloroquine, lopinavir/ritonavir, ivermectin and IL-6 receptor blockers can be accessed via the WHO website (2). Guidelines regarding the use of drugs to prevent (rather than treat) COVID-19 are included in a separate document, [WHO Living guideline: Drugs to prevent COVID-19](#), that can be accessed via the [WHO website](#) and the [BMJ](#) (3).

### Timing

This guidance is living – dynamically updated and globally disseminated once new evidence warrants a change in recommendations (21). The aim is for a 6-week timeframe from the public availability of trial data that trigger the guideline development process to WHO publication, while maintaining standards for trustworthy guidelines (WHO Handbook for guideline development) (22)(23).

### Stepwise approach

Here we outline the approach, involving simultaneous processes, taken to improve efficiency and timeliness of development and dissemination of living, trustworthy guidance.

#### *Step 1: Evidence monitoring and mapping and triggering of evidence synthesis*

Comprehensive daily monitoring of all emerging RCTs occurs on a continuous basis, within the context of the living systematic review and NMA, using experienced information specialists, who review all relevant information sources for new RCTs addressing interventions for COVID-19. Incorporating pre-print data, which have not yet undergone peer review, promote rapid data sharing in a public health emergency and its inclusion can accelerate the assessment and clinical use of COVID-19 therapeutic interventions. Guidelines are periodically updated to assess data that have undergone peer review in the intervening period and new data. Once practice-changing evidence, or increasing international interest, are identified, the WHO Therapeutics Steering Committee triggers the guideline development process. The trigger for producing or updating specific recommendations is based on the following (any of the three may initiate a recommendation):

- likelihood to change practice;
- sufficient RCT data on therapeutics to inform the high-quality evidence synthesis living systematic review;
- relevance to a global audience.

#### *Step 2: Convening the GDG*

The pre-selected expert GDG (see Section 9) convened on two occasions to address casirivimab and imdevimab. The first meeting, held on 27 May 2021, reviewed the basics of GRADE methodology including formulating population, intervention, comparator, outcome (PICO) questions and subgroups of interests, and prioritization of patient-important outcomes. Subsequent to the meeting, the GDG participated, through email correspondence, in a survey that elicited their views of the decrease in hospitalization that would prompt patients with non-severe COVID-19 to seek treatment with casirivimab and imdevimab. At the second meeting, held on 29 July, 2021, the GDG reviewed analyses, including pre-specified subgroup analyses presented in summary of findings tables, and considered an individual patient perspective and feasibility issues specific to this intervention, and formulated recommendations for both non-severe and severe and critical patients.

#### *Step 3: Evidence synthesis*

The living systematic review/NMA team, as requested by the WHO Therapeutics Steering Committee, performed an independent systematic review to examine the benefits and harms of the intervention (5). The systematic review team includes systematic review experts, clinical experts, clinical epidemiologists and biostatisticians. Team members have expertise in GRADE methodology and rating certainty of evidence specifically in NMAs. The NMA team considered deliberations from the initial GDG meeting, specifically focusing on the outcomes and subgroups prioritized by the GDG. The methods team rated credibility of subgroups using the ICEMAN tool (24).

#### *Step 4: Final recommendations*

The GRADE approach provided the framework for establishing evidence certainty and generating both the direction and strength of recommendations (25)(26). While *a priori* voting rules informed procedures if the GDG failed to reach consensus, these procedures proved unnecessary for this recommendation.

The following key factors informed transparent and trustworthy recommendations:

- absolute benefits and harms for all patient-important outcomes through structured evidence summaries (e.g. GRADE summary of findings tables) (27);
- quality/certainty of the evidence (25)(28);
- values and preferences of patients (29);
- resources and other considerations (including considerations of feasibility, applicability, equity) (29);
- effect estimates and confidence intervals for each outcome, with an associated rating of certainty in the evidence, as presented in summary of findings tables. If such data are not available, the GDG reviews narrative summaries (27);
- recommendations are rated as either conditional or strong, as defined by GRADE. If the GDG members disagree regarding the evidence assessment or strength of recommendations, WHO will apply voting according to established rules (26)(29).

*Step 5: External and internal review*

The WHO guideline was externally reviewed (see Section 9) and approved by the WHO GRC.

## 5. The latest evidence

This section outlines what information the GDG requested and used in making their recommendation for casirivimab and imdevimab.

### Mechanism of action

Casirivimab and imdevimab are two fully human antibodies (REGN10933 and REGN10987). Their mechanism of action is very plausible: they bind to the SARS-CoV-2 spike protein (30) and have demonstrated antiviral activity in rhesus macaques and Syrian golden hamsters (31). Pharmacokinetic data in patients with non-severe COVID-19 show that antiviral concentrations of both antibodies are achieved and maintained for at least 28 days after intravenous administration of the combination at a total dose of 1200 mg (600 mg each antibody) or above (10). Antiviral concentrations are also achieved and maintained using a subcutaneous total dose of 1200 mg (600 mg of each antibody) in uninfected individuals for prophylaxis (32). Half-lives range from 25 to 37 days for both antibodies. Data are currently unavailable for the pharmacokinetics of casirivimab and imdevimab in severe and critical COVID-19, which are important because serum concentrations of other monoclonal antibodies have been reported to be lower during systemic inflammation and correlated with albumin and CRP levels (33). Data available also suggest that when delivered in combination, activity remains for currently circulating variants of concern (34).

While the mechanism is plausible, it was postulated that administration might have differential effects in patients who have produced their own anti-SARS-CoV-2 spike protein antibodies (hereafter seropositive) compared with those who have not (hereafter seronegative). It was hypothesized that effects might be larger, or restricted to, seronegative individuals who have not yet mounted an effective antibody response.

### Benefits and harms

The GDG members prioritized outcomes (rating from 9 [critical] to 1 [not important] ) in patients with non-severe COVID-19 and in patients with severe and critical COVID-19, taking a patient perspective (Tables 1 and 2 below). The GDG's questions were structured using the PICO format (see evidence profile under the recommendations). These prioritized outcomes were used to update the LNMA (7).

### Baseline risk estimates

The evidence summaries that informed the guideline recommendations report the anticipated absolute effects of casirivimab and imdevimab compared with usual care across all patient-important outcomes. The absolute effects of treatment are informed by the prognosis (i.e. baseline risk estimates) combined with the relative estimates of effects (e.g. RR, OR) obtained from the LNMA.

### Values and preferences

We had insufficient information to provide the GDG with an evidence-based description of patient experiences or values and preferences regarding treatment decisions for COVID-19 drug treatments. The GDG therefore relied on their own judgments of what well-informed patients would value after carefully balancing the benefits, harms and burdens of treatment. Judgments on values and preferences were crucially informed through the experiences of former COVID-19 patients, represented in the GDG.

The GDG agreed that the following values and preferences would be typical of well-informed patients:

- Most patients would be reluctant to use a medication for which the evidence left high uncertainty regarding effects on outcomes they consider important. This was particularly so when evidence suggested treatment effects, if they do exist, are small, and the possibility of important harm remains.
- In an alternative situation with larger benefits and less uncertainty regarding both benefits and harms, more patients would be inclined to choose the intervention.

### Patients with non-severe illness

#### Selecting and rating the importance of outcomes

GDG members prioritized outcomes from the perspective of patients with non-severe illness (Table 1).

**Table 1. GDG outcome rating from the perspective of patients with non-severe illness.**

Outcome	Mean	SD	Range
Admission to hospital	8.5	0.7	7-9
Death	8.1	1.9	3-9
Quality of life	7.5	1.3	5-9

Outcome	Mean	SD	Range
Serious adverse effects (e.g. adverse events leading to drug discontinuation)	7.4	1.8	3-9
Time to symptom resolution	7.3	1.7	4-9
Duration of hospitalization	6.6	0.9	5-8
Duration of oxygen support	6.6	1.2	5-9
Need for invasive mechanical ventilation	5.9	2.3	1-8
New non-SARS-CoV-2 infection	5.6	2.1	3-9
Time to viral clearance	5.5	2.4	1-9
Duration of invasive mechanical ventilation	5.4	2.1	1-8

SD: standard deviation.

Note: 7 to 9 – critical; 4 to 6 – important; 1 to 3 – of limited importance.

### Evidence summary

The LNMA evidence summary (7) was informed by four trials that enrolled 4722 patients with non-severe illness (9)(10). All trials were registered and presented in preprints. [Table 3](#) shows trial characteristics.

Casirivimab and imdevimab probably reduces admission to hospital (moderate certainty evidence), the outcome was rated by the GDG of the highest importance for patients with non-severe COVID-19. The relative reduction in hospitalization (OR 0.29; 95% CI: 0.17–0.48) results in 39 fewer hospitalizations per 1000 patients (95% CI: 35 fewer to 21 fewer) when using the baseline risk of hospitalization in the three trials (4.2%). The evidence certainty was rated down to moderate because of concerns about decreased efficacy against emerging SARS-CoV-2 variants. The absolute benefit in hospital reduction will be greatest in those at highest risk for hospitalization and lower for the majority of the population at low risk. Casirivimab and imdevimab probably also reduces duration of hospitalization with a best estimate of a reduction from 9.6 to 8.2 days (mean difference [MD] 1.4 fewer days; 95% CI: 4.6 fewer to 1.8 more; moderate certainty evidence). The intervention results in very few allergic reactions and severe adverse events.

Concerning mortality, pooled data from 4722 patients in the four RCTs showed trivial or no effects of casirivimab and imdevimab (moderate certainty evidence). The GDG rated down the certainty of evidence for indirectness: the absolute risk of mortality in the overall trial population was very low (2 in 1000) and it is still possible that there is a small but important mortality reduction in patients at greatest risk of hospitalization. The conclusion is similar for mechanical ventilation based on 3432 patients with a very low baseline risk for ventilation of 4 in 1000.

### Subgroup analysis

We found no evidence of subgroup effects on age or time from onset of illness in patients with non-severe COVID-19.

### Baseline risk estimates (prognosis of patients with COVID-19) informing absolute estimates of effect

For the non-severe COVID-19 patients, we used the median of the control arm of the four RCTs that contributed to the evidence. For hospital admission, the key outcome driving the recommendation in favour of casirivimab and imdevimab, this gave a baseline risk of 4.2% (42 in 1000). These trials recruited patients at elevated risk of being hospitalized, to increase statistical power in detecting potential treatment effects. This means that the baseline risk of 4.2% is appreciably higher than the risk for many patients with non-severe COVID-19. Furthermore, the risks vary widely across patients, and the absolute benefit of administration of the intervention will be highly dependent on individual risk.

### Values and preferences

For the non-severe illness, the limited availability of casirivimab and imdevimab in relation to the number of infected individuals proved a major concern. For non-severe illness, GDG members completed a survey in which they provided their view regarding the magnitude of reduction in hospitalization that would prompt patients to use casirivimab and imdevimab. The panel responses suggested that the majority of patients with a risk of hospitalization above 10%, and thus an absolute risk reduction of approximately 6%, would choose to receive treatment while a majority of those below that risk level would decline treatment. Large majorities of patients with risks substantially higher than 10% would choose to receive treatment and large majorities of those with substantially lower risks would decline.

### Patients with severe or critical illness

## Selecting and rating the importance of outcomes

GDG members prioritized outcomes from the perspective of patients with severe or critical illness (Table 2).

**Table 2. GDG outcome rating from the perspective of patients with severe and critical illness.**

Outcome	Mean	SD	Range
Death	9.0	0	9
Need for invasive mechanical ventilation	8.2	0.9	6-9
Duration of invasive mechanical ventilation	7.6	0.9	6-9
Quality of life	6.9	1.3	5-9
Duration of hospitalization	6.7	1.2	4-9
Serious adverse effects (e.g. adverse events leading to drug discontinuation)	6.7	1.8	3-9
Time to symptom resolution	6.5	1.6	4-9
New non-SARS-CoV-2 infection	6.4	1.8	3-9
Duration of oxygen support	6.3	1.3	4-9
Time to viral clearance	4.7	2.3	1-9

SD: standard deviation.

Note: 7 to 9 – critical; 4 to 6 – important; 1 to 3 – of limited importance.

## Evidence summary

The NMA evidence summary was informed by one large trial (RECOVERY) in patients with severe and critical illness that enrolled 9785 patients, most of whom received corticosteroids (11). The trial was registered and presented in preprints. Table 3 shows trial characteristics.

In the overall population of patients with severe and critical COVID-19, not taking serological status into account, it remains uncertain whether casirivimab and imdevimab result in an important effect on mortality (OR 0.94; 95% CI: 0.86–1.03; absolute effect estimate 8 fewer per 1000 patients; 95% CI: 18 fewer to 4 more; low certainty evidence). The evidence was rated as low certainty because of imprecision and indirectness; a high likelihood that casirivimab and imdevimab have, in the seronegative and seropositive patients included in the overall group, very different effects (see below). The evidence on need for mechanical ventilation and duration of hospitalization was rated as very low certainty, adding risk of bias due to lack of blinding as another concern.

## Subgroup analysis

A highly credible subgroup effect demonstrated that casirivimab and imdevimab likely reduces mortality in patients who are seronegative but not in those who are seropositive. Based on data from 3153 patients in the RECOVERY trial, the anticipated relative risk reduction of death in seronegative patients receiving casirivimab and imdevimab was 0.85 (95% CI: 0.76–0.95; absolute effect estimate 39 fewer per 1000; 95% CI: 62 fewer to 13 fewer; moderate quality evidence due to concerns with imprecision and indirectness due to possible new SARS-CoV-2 variants in the future where benefit may change). In the seronegative patients, the intervention may reduce the need for mechanical ventilation (RR 0.87; 95% CI: 0.77–0.98; absolute effect estimate 42 fewer per 1000; 95% CI: 74 fewer to 6 fewer; low certainty due to serious risk of bias, indirectness, and imprecision).

The credibility of the subgroup effect was evaluated using the ICEMAN tool (24). The credibility of the subgroup effect was strongly supported by: an *a priori* hypothesis with a specified direction; a small number of such hypotheses; evidence based on a within-study comparison; a suggestion of a similar subgroup effect in mechanical ventilation; and an interaction p-value of 0.001. Figure 1 presents the forest plot depicting the point estimate and confidence interval around the effects on mortality in the seropositive and seronegative, demonstrating benefit in the seronegative, a point estimate suggesting harm in the seropositive, and no overlap in the confidence intervals, a result corresponding to the  $p=0.001$  in the test of interaction (11).

**Figure 1. Mortality, in seropositive and seronegative patients with severe and critical COVID-19**

Outcome, subgroup	REGEN-COV	Usual care		RR (95% CI)
<b>Death within 28 days (<math>\chi^2_1 = 10.1</math>; <math>p = 0.001</math>)</b>				
Seronegative	396/1633 (24%)	451/1520 (30%)		0.80 (0.70–0.91)
Seropositive	411/2636 (16%)	383/2636 (15%)		1.09 (0.95–1.26)
Unknown	137/570 (24%)	192/790 (24%)		0.98 (0.78–1.22)
<b>All participants</b>	<b>944/4839 (20%)</b>	<b>1026/4946 (21%)</b>		<b>0.94 (0.86–1.03)</b>

CI: Confidence interval, RR: Relative risk.

Very low certainty evidence raises the possibility of shorter hospitalization in seronegative patients. Aside from the reported subgroup effects on serological status, we found no evidence of subgroup effects on age, time from onset of illness, and severity (comparing severe and critically ill patients).

#### Baseline risk estimates (prognosis of patients with COVID-19) informing absolute estimates of effect

In severe and critical COVID-19 patients, for the critical outcome of mortality, the applied baseline risk estimate was 13% (130 in 1000). As for other related recommendations in this guideline, the estimate is derived from the SOLIDARITY trial for severe and critical patients adjusted for treatment effects of corticosteroids. To inform baseline risk estimates for mortality in the seronegative patients, we identified the control arm of the RECOVERY trial as the best source. For the seronegative, risk of death in both severe (26%; 260 per 1000) and critical (46%; 460 per 1000) was substantially higher than for the overall population. Thus, seronegative patients represent a very high risk population, leading to substantial absolute risk reductions in mortality (3.9% in the severe and 6.9% in the critical) despite the modest 15% relative risk reduction.

#### Values and preferences

Although the GDG focused on an individual patient perspective, they also considered a population perspective in which feasibility, acceptability, equity and cost are important considerations. In this case, feasibility concerns played an important role in the conditional recommendation. For the severe and critical, both limited availability of therapeutics and the requirement for serological testing as part of clinical decision-making to identify the seronegative patients proved important.

## 6. Who do the recommendations apply to?

### Info Box

The guideline for COVID-19 therapeutics applies to all patients with COVID-19. For some drugs, recommendations may differ for different patient populations, for example based on the severity of COVID-19 disease. The GDG used the WHO severity definitions based on clinical indicators, adapted from WHO COVID-19 disease severity categorization (see below) (12). These definitions avoid reliance on access to health care to define patient subgroups.

### WHO severity definitions

- **Critical COVID-19** – Defined by the criteria for acute respiratory distress syndrome (ARDS), sepsis, septic shock, or other conditions that would normally require the provision of life-sustaining therapies such as mechanical ventilation (invasive or non-invasive) or vasopressor therapy.
- **Severe COVID-19** – Defined by any of:
  - Oxygen saturation < 90% on room air;
  - in adults, signs of severe respiratory distress (accessory muscle use, inability to complete full sentences, respiratory rate > 30 breaths per minute), and, in children, very severe chest wall indrawing, grunting, central cyanosis, or presence of any other general danger signs (inability to breastfeed or drink, lethargy or reduced level of consciousness, convulsions) in addition to the signs of pneumonia.
- **Non-severe COVID-19** – Defined as absence of any criteria for severe or critical COVID-19.

**Caution:** The GDG noted that the oxygen saturation threshold of 90% to define severe COVID-19 was arbitrary and should be interpreted cautiously when used to define disease severity. For example, clinicians must use their judgment to determine whether a low oxygen saturation is a sign of severity or is normal for a given patient with chronic lung disease. Similarly, a saturation 90–94% on room air is abnormal (in patient with normal lungs) and can be an early sign of severe disease, if patient is on a downward trend. Generally, if there is any doubt, the GDG suggested erring on the side of considering the illness as severe.

The infographic illustrates these three disease severity groups and key characteristics to apply in practice.

### Population

This recommendation applies only to people with these characteristics:

### Disease severity

Infographic co-produced by the BMJ and MAGIC; designer Will Stahl-Timmins (see [BMJ Rapid Recommendations](#)).

## 7. Recommendations for therapeutics

### 7.1 Casirivimab and imdevimab (neutralizing monoclonal antibodies)

For patients with non-severe COVID-19 (who do not meet criteria for severe or critical infection)

Conditional recommendation

New

We suggest treatment with casirivimab and imdevimab, conditional to those at highest risk of hospitalization.

- *Whereas casirivimab and imdevimab achieves a substantial reduction in the relative risk of hospitalization, the absolute benefit will be trivial or unimportant in absolute terms for all but those at highest risk for which the intervention should be reserved.*
- *The panel identified a risk beyond 10% of being hospitalized for COVID-19 to represent a threshold at which most people would want to be treated with casirivimab and imdevimab.*
- *In the absence of credible tools to predict risk for hospitalization in people infected with COVID-19, typical characteristics of people at highest risk include lack of vaccination, older people, or those with immunodeficiencies and/or chronic diseases (e.g. diabetes).*

#### Practical Info

**Dosing and administration route:** Intravenous total dose of the monoclonal antibody combination differed in the non-severe trials, ranging from total dose 1200 mg–8000 mg (600 mg–4000 mg each antibody), demonstrating efficacy at all doses, including the lowest tested, 1200 mg total dose (600mg of each antibody). In the face of limited access and resource considerations, health systems will face choices concerning dose of casirivimab and imdevimab as well as intravenous or subcutaneous injections. Please see the acceptability and feasibility section (under Evidence to Decision) for some deliberations to help in making these choices within the possible range of 1200 mg–2400 mg total dose.

**Monitoring:** Although the available trials have not convincingly shown that casirivimab and imdevimab results in allergic reactions, the possibility remains. To be administered through an intravenous line containing a sterile in-line or add-on 0.2 micron filter. Following administration, patients should undergo monitoring for severe anaphylaxis.

#### Evidence To Decision

##### Benefits and harms

In non-severe patients, casirivimab and imdevimab probably reduces the risk of hospitalization and duration of symptoms. Casirivimab and imdevimab is unlikely to have serious adverse effects, including allergic reactions.

##### Certainty of the Evidence

The unavailability of an empirically developed and validated risk prediction tool for establishing patients' risk of hospitalization represents the major source of indirectness for which the GDG rated down the certainty of the evidence. In addition, the GDG felt that there was some indirectness because of the possible emergence of variants in which effectiveness may be reduced. The GDG thus rated down the certainty of evidence to moderate for hospitalization and duration of symptoms. The GDG rated down evidence certainty to moderate for allergic reactions because of imprecision but considered the finding of no serious adverse effects to represent high certainty evidence.

##### Preference and values

Applying the agreed values and preferences (see Section 5), the GDG inferred that almost all well-informed patients at typical low risk of hospitalization would decline casirivimab and imdevimab and only those at higher risk (e.g. unvaccinated, older, or immunosuppressed) would choose the treatment.

##### Resources and other considerations

##### Acceptability and feasibility

The GDG noted that casirivimab and imdevimab is unlikely to be available for all individuals who, given the option, would choose to receive the treatment. This further supports the guidance that casirivimab and imdevimab be reserved for those at highest risk of hospitalization.

Major feasibility challenges include limited production of casirivimab and imdevimab and, for outpatients, the requirement for intravenous administration. Regarding intravenous administration, it is likely that specialized clinics with adequate amounts of the antibodies and personnel who will ensure safe and effective administration of the intervention will be required. For the intervention to achieve substantial use, health systems will have to address these challenges.

**Choosing a dose:** Different doses of the monoclonal antibody combination were used in different trials, and health systems will face the choice of which dose to use and this can be informed by values and preferences. If one's priority is to ensure giving as many people as possible the opportunity to benefit from treatment, one might use the lowest effective dose offered in the studies of non-severe patients, 1200 mg total dose (600 mg of each antibody) (35). If one's priority is on ensuring effectiveness in every individual who receives treatment, and minimizing the risk of emergence of resistance, one might use a higher total intravenous dose of 2400 mg (1200 mg of each antibody).

**Administration route:** A similar value and preference issue arises in choosing between intravenous administration – used in the four trials included in the LNMA (from a larger adaptive randomised master protocol)(10) – and subcutaneous administration, which has been used in the prophylactic trial (32). Intravenous administration will achieve maximum drug concentrations faster than subcutaneous administration; however, both will achieve exposure above the proposed therapeutic threshold. If one's priority is to ensure maximum effectiveness in every individual who receives treatment, one might choose intravenous administration. If one's priority is, in the face of practical difficulties of widespread intravenous administration in the community, to ensure giving as many people as possible the opportunity to benefit from treatment, one might ensure the availability of subcutaneous administration as an alternative. Volumes that can be administered subcutaneously are limited to the lowest dose, which is a total dose 1200 mg (600 mg of each antibody).

### Justification

A combination of the evidence, values and preferences, and feasibility contributed to the conditional recommendation for the use of casirivimab and imdevimab only in patients with non-severe COVID-19 at highest risk of hospitalization. Although there is moderate certainty evidence of a substantial relative risk reduction in hospitalization, only a minority of patients who are at highest risk are likely to achieve important benefit. In routine care of those with non-severe COVID-19, there is a lack of tools to reliably identify those at highest risk of hospitalization. This clinical complexity, combined with the limited availability of the drug and need for parenteral administration route for a group of patients who are typically cared for in the community, present a range of challenges for care that need to be addressed by health care systems.

### Applicability

The applicability of this recommendation to children is currently uncertain, as the included RCTs enrolled adults. The GDG had no reason to think that children with COVID-19 would respond any differently to treatment with casirivimab and imdevimab. However, the risk of hospitalization in children is generally extremely low and the GDG inferred that in the absence of immunosuppression or another significant risk factor children should not receive the intervention.

### Clinical Question/ PICO

### For patients with severe or critical COVID-19

#### Conditional recommendation

New

We suggest treatment with casirivimab and imdevimab, under the condition that the patient has seronegative status.

- *With benefits of casirivimab and imdevimab observed only in patients with seronegative status, clinicians will need to identify these patients by credible tests available at the point of care to appropriately apply this recommendation (see Evidence to Decision section).*
- *Treatment with casirivimab and imdevimab is in addition to the current standard of care, which includes corticosteroids and IL-6 receptor blockers.*

### Practical Info

**Dosing and administration route:** Intravenous dosing of the monoclonal antibody combination in the RECOVERY trial that enrolled severe and critical COVID-19 was a total dose of 8000 mg (4000 mg for each antibody), whereas the dose differed in the four trials in non-severe patients (from a larger adaptive randomised master protocol), ranging from intravenous total dose of 1200 mg–8000 mg. In the face of limited access and resource considerations, health systems will face a choice concerning the dose of casirivimab and imdevimab. Please see the acceptability and feasibility section (under Evidence to Decision) for some deliberations to help in making these choices within the possible range of 2400 mg-8000 mg total dose.

**Diagnostic testing:** Tests to identify patients with seronegative status at the time patients present with severe or critical COVID-19 warrant rapid serological tests with adequate performance characteristics. Health care systems would need to implement such tests, as outlined in the acceptability and feasibility section.

**Monitoring:** Although the available trials have not convincingly shown that casirivimab and imdevimab results in allergic reactions, the possibility remains. To be administered through an intravenous line containing a sterile in-line or add-on 0.2 micron filter. Following infusion, patients should undergo monitoring for allergic reactions.

### Evidence To Decision

#### Benefits and harms

In the overall population of patients with severe and critical COVID-19, casirivimab and imdevimab may not have an impact on mortality and the impact on mechanical ventilation and duration of hospitalization is very uncertain.

A credible subgroup effect demonstrated that casirivimab and imdevimab probably reduce mortality in patients who are seronegative, with the absolute effects ranging from 39 fewer per 1000 (95% CI: 62 fewer–13 fewer) in the severely ill to 69 fewer (95% CI: 110 fewer–23 fewer) in the critically ill. In seronegative patients, the intervention possibly reduces the

need for mechanical ventilation (absolute effect estimate 42 fewer per 1000; 95% CI: 74 fewer–6 fewer). Aside from the credible subgroup effect for serological status, we found no evidence of subgroup effects on age or time from onset of illness in the non-severe, or on age, time from onset of illness, and severity in the severe and critically ill.

### Certainty of the Evidence

In patients with severe and critical COVID-19, evidence for mortality was of low certainty because of imprecision and high likelihood that casirivimab and imdevimab have, in the seronegative and seropositive patients included in the overall group, very different effects. In this population, the evidence regarding the impact of the intervention on need for mechanical ventilation and duration of hospitalization was very low certainty given additional concerns with risk of bias.

For patients with severe and critical COVID-19 who are seronegative, evidence for mortality was rated as moderate as a result of concerns regarding imprecision (the confidence interval includes effects as small as 14 in 1000 that some patients may perceive as unimportant) and indirectness (variants may emerge in which casirivimab and imdevimab antibodies may have reduced effect). For mechanical ventilation, the GDG noted risk of bias from lack of blinding as an additional concern, resulting in low certainty evidence. For duration of hospitalization, the GDG also found very serious imprecision, resulting in very low certainty evidence.

### Preference and values

Applying the agreed values and preferences (see Section 5), the GDG inferred that most if not all well-informed patients with severe or critical COVID-19 and seronegative status would choose to receive casirivimab and imdevimab. Other patients – those whose are seropositive or whose status is uncertain – are likely to decline the intervention.

### Resources

#### Cost and availability

Given the cost and availability of casirivimab and imdevimab, and the challenges associated with serological testing, the obstacles to ensuring access in low- and middle-income countries may prove formidable. Thus, the panel's suggestion that patients who are seronegative receive the intervention may exacerbate health inequity. On the other hand, given the demonstrated benefits for patients, the recommendations should provide a stimulus to engage all possible mechanisms to improve global access to the intervention. Individual countries may formulate their guidelines considering available resources and prioritize treatment options accordingly.

#### Acceptability and feasibility

Supply of casirivimab and imdevimab are likely to be limited, raising accessibility and possibly rationing challenges. In addition, benefit requires identification of serological status at the time patients present with severe or critical COVID-19. The availability of rapid and accurate serological tests as well as dosing and administration route for the drug are therefore key factors to consider for health care systems.

**Rapid serological tests:** Tests with performance characteristics similar to the reference standard test used to characterize seronegative patients in the RECOVERY trial, i.e. the Oxford fluorescent-based ELISA assay for serum IgG against the SARS-CoV-2 spike protein, with an arbitrary cut-off determined by a panel of positive controls, are available and potentially affordable. Some lateral flow assays may be suitable and can usually be performed in several minutes (36)(37)(38). Health care systems must, however, gain expertise in choosing and implementing a rapid test or test, choosing those most applicable to their setting..

**Choosing a dose:** The clinical trial in severe and critical patients (RECOVERY) tested a total dose of 8000 mg (4000 mg of each antibody) casirivimab and imdevimab; clinical trials in non-severe patients have used total doses of 1200 mg–8000 mg (600 mg–4000 mg of each) with similar effects on decreasing the need for hospitalization. Pharmacokinetic profiles of casirivimab and imdevimab in non-severe with COVID-19 are available at total doses of 1200 mg–8000 mg (600 mg–4000 mg of each monoclonal antibody) (10). This study demonstrated that the target therapeutic concentrations were achieved rapidly in serum and maintained for 28 days even at the lowest total dose of 1200 mg (600 mg of each antibody), although serum concentrations of drug were noted to vary considerably between individuals. Therefore, using doses lower than used

in the RECOVERY trial (8000 mg total dose) for treatment of severely and critically ill patients may achieve the same benefit. On the other hand, it is theoretically plausible but untested that pharmacokinetic differences in severe and critical patients, when compared with non-severe, may reduce drug exposure (see Mechanism of Action - Section 5). This would increase the risk of sub-optimal drug exposure in some individuals, which in turn could increase the risk of therapeutic failure and the emergence of viral resistance.

In the absence of clinical data on treatment of severe and critical patients with doses lower than 8000 mg, making a choice on which dose to use can be informed by values and preferences. If one's priority is on ensuring effectiveness in every individual who receives treatment, and minimizing the risk of emergence of resistance, one might use the total intravenous dose of 8000 mg (4000 mg of each antibody). If one's priority is, in the face of limited drug availability and high cost, on giving as many people as possible an opportunity to benefit from treatment, one might use an intravenous dose as low as a total of 2400 mg (1200 mg of each antibody).

At a time of drug shortage, it may be necessary to prioritize use of casirivimab and imdevimab through clinical triage. One possibility is to prioritize patients with the highest baseline risk for mortality (e.g. those with critical disease over those with severe disease), in whom the absolute benefit of treatment is therefore greatest. For example, despite consistent relative effects (OR 0.85 for mortality) with casirivimab and imdevimab in seronegative patients, the absolute risk reduction for mortality in the critically ill would be 69 fewer deaths per 1000 (95% CI: 110 to 23 fewer deaths) and in the severely ill would be 39 fewer deaths per 1000 (95% CI: 62 to 13 fewer deaths).

Other suggestions for prioritization, which lack direct evidence, include focusing on patients with an actively deteriorating clinical course and avoiding casirivimab and imdevimab therapy in those with established multi-organ failure (in whom the benefit is likely to be smaller).

### Justification

In patients with severe or critical illness, the conditional recommendation in favour of casirivimab and imdevimab use reflects the likelihood that any benefits are restricted to patients who are seronegative. In the RECOVERY trial, which provided all the evidence in severe and critical patients, serological status at baseline was assessed in a pre-planned but retrospective analysis using a laboratory-based anti-spike protein assay. In order to translate the trial findings into clinical practice, assessment of serological status will need to become integrated into a clinical decision pathway *before* treatment is administered. This implies rapid identification of serological status at the time of presentation of severe or critical illness to guide use in this population.

Several rapid and relatively inexpensive tests with adequate performance characteristics are available and should see increasing use in settings in which casirivimab and imdevimab is available for administration to these patients.

### Applicability

None of the included RCTs enrolled children, and therefore the applicability of this recommendation to children is currently uncertain. Fortunately, very few children become critically ill with COVID-19. For those who do and are seronegative, it is possible they may benefit from casirivimab and imdevimab. Lack of data precluded the GDG from making specific recommendations for other special populations, such as pregnant women.

### Clinical Question/ PICO

Critical or severe disease	(CI 95% 0.86 – 1.03) Based on data from 9,785 patients in 1 studies. (Randomized controlled)	per 1000  Difference:	per 1000  <b>8 fewer per 1000</b> ( CI 95% 18 fewer – 4 more )	Due to serious indirectness and imprecision <sup>1</sup>	imdevimab may not have an important effect on mortality.
Mechanical ventilation	Odds Ratio 0.95 (CI 95% 0.87 – 1.04) Based on data from 6,637 patients in 1 studies. (Randomized controlled)	<b>86</b> per 1000  Difference:	<b>82</b> per 1000  <b>4 fewer per 1000</b> ( CI 95% 11 fewer – 3 more )	<b>Very low</b> Due to serious risk of bias, indirectness, and imprecision <sup>2</sup>	The impact on mechanical ventilation is very uncertain.
Allergic reactions	Based on data from 15,406 patients in 4 studies. (Randomized controlled)	<b>3</b> per 1000  Difference:	<b>9</b> per 1000  <b>6 more per 1000</b> ( CI 95% 1 fewer – 29 more )	<b>Moderate</b> Due to serious imprecision <sup>3</sup>	Casirivimab and imdevimab probably do not result in an important increase in allergic reactions.
Adverse effects leading to drug discontinuation	Based on data from 5,284 patients in 4 studies. (Randomized controlled)	<b>2</b> per 1000  Difference:	<b>1</b> per 1000  <b>1 fewer per 1000</b> ( CI 95% 2 fewer – 1 more )	<b>High</b>	Casirivimab and imdevimab do not result in an important increase in adverse effects leading to drug discontinuation.
Duration of hospitalization	Based on data from: 9,785 patients in 1 studies. (Randomized controlled)	Patients in both groups had the same median duration of hospitalization (10 days).		<b>Very low</b> Due to serious risk of bias and very serious imprecision <sup>4</sup>	The impact on duration of hospitalization is very uncertain.

1. **Inconsistency: no serious. Indirectness: serious. Imprecision: serious. Publication bias: no serious.**
2. **Risk of Bias: serious. Inconsistency: no serious. Indirectness: serious. Imprecision: serious. Publication bias: no serious.**
3. **Imprecision: serious.**
4. **Risk of Bias: serious. Inconsistency: no serious. Indirectness: no serious. Imprecision: very serious. Publication bias: no serious.**

## 7.2 IL-6 receptor blockers (published 6 July 2021)

### Info Box

The recommendation concerning IL-6 receptor blockers (tocilizumab or sarilumab) was published on 6 July 2021 as the [fifth version](#) of the WHO living guideline and in the BMJ as [Rapid Recommendations](#). No changes were made for the IL-6 receptor blocker recommendation in this sixth version of the guideline. Please view the section text for a summary of the evidence requested to inform the recommendation.

**Recommended**

We recommend treatment with IL-6 receptor blockers (tocilizumab or sarilumab) for patients with severe or critical COVID-19 infection.

*Corticosteroids have previously been strongly recommended in patients with severe and critical COVID-19 (2), and we recommend patients meeting these severity criteria should now receive both corticosteroids and IL-6 receptor blockers.*

**Practical Info**

**Route:** IL-6 receptor blockers are administered intravenously for the treatment of patients with severe or critical COVID-19; subcutaneous administration is not used in this case. IL-6 receptor blocker therapy should be administered in combination with systemic corticosteroids, which may be administered both orally and intravenously, with due consideration to their high bioavailability but possible malabsorption in the case of intestinal dysfunction with critical illness.

**Duration:** Tocilizumab and sarilumab are administered as single intravenous doses, typically over 1 hour. A second dose may be administered 12 to 48 hours after the first dose; this was offered variably in major clinical trials at the discretion of treating clinicians if a clinical response was felt to be inadequate. Duration of concurrent systemic corticosteroids is typically up to 10 days, though may vary between 5 and 14 days.

**Dose:** Tocilizumab is dosed at 8 mg per kilogram of actual body weight, up to a maximum of 800 mg. Sarilumab is most commonly dosed at 400 mg, consistent with what was used in REMAP-CAP. Renal dose adjustment is not currently warranted for either drug.

**Monitoring:** Routine bloodwork including neutrophil count, platelets, transaminases, and total bilirubin should be checked prior to initiation of therapy. All patients should be monitored for signs and symptoms of infection, given the increased risk with immunosuppression in addition to systemic corticosteroids. Patients on longer-term IL-6 receptor blocker therapy are at risk of active tuberculosis, invasive fungal infections and opportunistic pathogens. Risks and benefits of therapy should be considered carefully in patients with any active, severe infection other than COVID-19; caution is advised when considering the use of tocilizumab in patients with a history of recurring or chronic infections or with underlying conditions which may predispose them to infections.

**Timing:** IL-6 receptor blockers should be initiated with systemic corticosteroids; specific timing during hospitalization or the course of illness is not specified. That being said, IL-6 receptor blockers have been administered early in the course of hospitalization in the included trials and clinicians may consider this approach if possible. See section on resource implications, equity and human rights.

**Evidence To Decision****Benefits and harms**

IL-6 receptor blockers reduce mortality and need for mechanical ventilation based on high certainty evidence. Low certainty evidence suggests they may also reduce duration of mechanical ventilation and hospitalization (6)(39)(40).

The evidence regarding the risk of SAEs is uncertain. Low certainty evidence suggested that the risk of bacterial infections in the context of immunosuppression treatment with IL-6 receptor blockers may be similar to usual care (5). However the GDG had some concerns that, given the short-term follow-up of most trials and the challenges associated with accurately capturing adverse events such as bacterial or fungal infection, the evidence summary may under-represent the risks of treatment with IL-6 receptor blockers. Furthermore, the trials of IL-6 receptor blockers that inform this recommendation were mostly performed in high-income countries where the risk of certain infectious complications may be less than in some other parts of the world, and so the generalizability of the data on adverse events is unclear. We did not have any data examining differential risk of harm based on whether patients received one or two doses of IL-6 receptor blocker.

Subgroup analyses indicated no effect modification based on IL-6 receptor blocker drug (sarilumab or tocilizumab) or disease severity (critical vs severe) and therefore this recommendation applies to all adult patients with either severe or critical COVID-19 (24). We were unable to examine subgroups based on elevation of inflammatory markers or age due to insufficient trial data (see Section 5). Subgroup analyses evaluating baseline steroid use found greater benefit of IL-6

receptor blockers in patients receiving steroids compared with those who were not ( $p=0.026$ ), demonstrating that steroid use does not abolish and might enhance the beneficial effect of IL-6 receptor blockers. Since steroids are already strongly recommended in patients with severe and critical COVID-19, we did not formally evaluate the credibility of this subgroup analysis as there would be no rationale for a subgroup recommendation for patients not receiving corticosteroids.

### **Certainty of the Evidence**

Certainty of evidence was rated as high for mortality and need for mechanical ventilation. Certainty in duration of mechanical ventilation was rated as low due to serious risk of bias due to concerns regarding lack of blinding in included trials, and for imprecision as the lower limit of the confidence interval suggested no effect. Certainty in duration of hospitalization was rated as low due to serious risk of bias from lack of blinding in included trials, and for inconsistency related to differences in point estimates and lack of overlap in confidence intervals.

Certainty in SAEs was rated as very low due to risk of bias related to lack of blinding and ascertainment bias, and very serious imprecision due to very wide confidence intervals which did not rule out important benefit or harm; certainty in risk of bacterial or fungal infections was rated as low due to similar concerns regarding serious risk of bias and serious imprecision.

Certainty in evidence was rated as moderate when comparing the effect on mortality between tocilizumab and sarilumab due to issues with imprecision.

### **Preference and values**

Applying the agreed values and preferences (see Section 5), the majority of the GDG inferred that almost all well-informed patients would want to receive IL-6 receptor blockers. The benefit of IL-6 receptor blockers on mortality was deemed of critical importance to patients, despite the very low certainty around SAEs. The GDG anticipated little variation in values and preferences between patients for this intervention.

### **Resources and other considerations**

#### **Resource implications, equity and human rights**

The GDG noted that, compared with some other candidate treatments for COVID-19, IL-6 receptor blockers are more expensive and the recommendation does not take account of cost-effectiveness. Currently, access to these drugs is challenging in many parts of the world, and without concerted effort is likely to remain so, especially in resource-poor areas. It is therefore possible that this strong recommendation for IL-6 receptor blockers could exacerbate health inequity. On the other hand, given the demonstrated benefits for patients, it should also provide a stimulus to engage all possible mechanisms to improve global access to these treatments. Individual countries may formulate their guidelines considering available resources and prioritize treatment options accordingly.

At a time of drug shortage, it may be necessary to prioritize use of IL-6 receptor blockade through clinical triage (12). Many jurisdictions have suggested mechanisms for triaging use of these treatments. These include prioritizing patients with the highest baseline risk for mortality (e.g. those with critical disease over those with severe disease), in whom the absolute benefit of treatment is therefore greatest. For example, despite consistent relative effects (OR 0.86 for mortality) with IL-6 receptor blockers, the absolute risk reduction for mortality in the critically ill would be 31 fewer deaths per 1000 (95% CI: 11 to 47 fewer deaths) and in the severely ill would be 13 fewer deaths per 1000 (95% CI: 5 to 19 fewer deaths).

Other suggestions for prioritization, which lack direct evidence, include focusing on patients with an actively deteriorating clinical course and avoiding IL-6 receptor blocker therapy in those with established multi-organ failure (in whom the benefit is likely to be smaller).

#### **Acceptability and feasibility**

As IL-6 receptor blockers require intravenous administration, this treatment would be primarily indicated for patients with severe and critical COVID-19 who require hospitalization. IL-6 receptor blockers are relatively easy to administer, and only require one, or at most, two doses.

## Justification

When moving from evidence to the strong recommendation to use IL-6 receptor blockers (tocilizumab or sarilumab) in patients with severe or critical COVID-19, the GDG emphasized the high certainty evidence of improved survival and reduction in need for invasive mechanical ventilation (IMV). Additional trial data from REMAP-CAP (see latest evidence section) provided more conclusive evidence regarding the equivalence of tocilizumab and sarilumab.

The GDG acknowledged the uncertain data regarding SAEs and bacterial infections, but felt that the evidence of benefit for the two most important patient outcomes warranted a strong recommendation. Costs and access were important considerations and it was recognized that this recommendation could exacerbate health inequities. Hopefully this strong recommendation will provide impetus to address these concerns and ensure access across regions and countries. The GDG did not anticipate important variability in patient values and preferences, and judged that other contextual factors would not alter the recommendation (see Evidence to Decision).

## Subgroup analyses

The GDG did not find any evidence of a subgroup effect across patients with different levels of disease severity (severe vs. critical), or by IL-6 receptor blocker drug (tocilizumab vs. sarilumab).

There were insufficient data to assess subgroup effect by elevation of inflammatory markers or age. Although the GDG considered a subgroup analysis of patients receiving corticosteroids at baseline as compared with those that were not, the panel didn't see a need to consider subgroup recommendations for IL-6 receptor blockers in those not receiving corticosteroids as all severe and critical COVID-19 patients should be receiving corticosteroids (see previous strong recommendation below). Taken together, the GDG felt that the recommendation applies to both tocilizumab and sarilumab and all adult patients with severe or critical COVID-19.

## Applicability

None of the included RCTs enrolled children, and therefore the applicability of this recommendation to children is currently uncertain. However, the GDG had no reason to think that children with COVID-19 would respond any differently to treatment with IL-6 receptor blockers. This is especially true given tocilizumab is used in children safely for other indications including polyarticular juvenile rheumatoid arthritis, systemic onset of juvenile chronic arthritis, and chimeric antigen receptor T-cell induced cytokine release syndrome. Sarilumab is not approved in children, so if an IL-6 receptor blocker is used in this population, tocilizumab is preferred. The GDG also recognized that in many settings children are commonly admitted to hospital with acute respiratory illnesses caused by other pathogens; as a result, it may be challenging to determine who is ill with severe COVID-19, even with a positive test, and therefore likely to benefit from IL-6 receptor blockade. There were similar considerations in regard to pregnant women, with no data directly examining this population, but no rationale to suggest they would respond differently than other adults. The drug may, however, cross the placental membrane, although it is uncertain what effect transient immunosuppression in the fetus may have and this should be weighed against the potential benefit for the mother.

## Clinical Question/ PICO

**Population:** Patients with COVID-19 infection (severe and critical)  
**Intervention:** IL-6 inhibitor  
**Comparator:** Standard care

Outcome Timeframe	Study results and measurements	Comparator Standard care	Intervention IL-6 inhibitor	Certainty of the Evidence (Quality of evidence)	Plain language summary
Mortality (severe and critically ill patients)	Odds Ratio 0.86 (CI 95% 0.79 – 0.95) Based on data from 10,930 patients in 27 studies. <sup>1</sup> (Randomized controlled)	<b>130</b> per 1000  Difference:	<b>114</b> per 1000  <b>16 fewer per 1000</b> ( CI 95% 24 fewer – 6 fewer )	High	IL-6 inhibitors reduce mortality.

Outcome Timeframe	Study results and measurements	Comparator Standard care	Intervention IL-6 inhibitor	Certainty of the Evidence (Quality of evidence)	Plain language summary
Mechanical ventilation	Odds Ratio 0.72 (CI 95% 0.57 – 0.9) Based on data from 5,686 patients in 9 studies. <sup>2</sup> (Randomized controlled)	<b>86</b> per 1000  Difference:	<b>63</b> per 1000  <b>23 fewer per 1000</b> ( CI 95% 35 fewer – 8 fewer )	<b>High</b>	IL-6 inhibitors reduce need for mechanical ventilation.
Adverse events leading to drug discontinuation	Odds Ratio 0.5 (CI 95% 0.03 – 9.08) Based on data from 815 patients in 2 studies. <sup>3</sup> (Randomized controlled)	<b>9</b> per 1000  Difference:	<b>5</b> per 1000  <b>4 fewer per 1000</b> ( CI 95% 9 fewer – 67 more )	<b>Very low</b> Due to serious risk of bias and very serious imprecision <sup>4</sup>	The effect of IL-6 inhibitors on adverse events leading to discontinuation is uncertain.
Bacterial infections	Odds Ratio 0.95 (CI 95% 0.72 – 1.29) Based on data from 3,548 patients in 18 studies. (Randomized controlled)	<b>101</b> per 1000  Difference:	<b>96</b> per 1000  <b>5 fewer per 1000</b> ( CI 95% 26 fewer – 26 more )	<b>Low</b> Due to serious risk of bias and serious imprecision <sup>5</sup>	IL-6 inhibitors may not increase secondary bacterial infections.
Duration of mechanical ventilation	Lower better Based on data from: 1,189 patients in 10 studies. (Randomized controlled)	<b>14.7</b> (Mean)  Difference:	<b>13.5</b> (Mean)  <b>MD 1.2 lower</b> ( CI 95% 2.3 lower – 0.1 lower )	<b>Low</b> Due to serious risk of bias and serious imprecision <sup>6</sup>	IL-6 inhibitors may reduce duration of mechanical ventilation.
Duration of hospitalization	Lower better Based on data from: 6,665 patients in 9 studies. (Randomized controlled)	<b>12.8</b> (Mean)  Difference:	<b>8.3</b> (Mean)  <b>MD 4.5 lower</b> ( CI 95% 6.7 lower – 2.3 lower )	<b>Low</b> Due to serious risk of bias and serious inconsistency <sup>7</sup>	IL-6 inhibitors may reduce duration of hospitalization.

1. **Baseline/comparator:** Primary study[18]. Baseline risk for mortality and mechanical ventilation were derived from the WHO SOLIDARITY trial for patients with severe and critical COVID-19, adjusted for corticosteroids as part of standard of care (16% baseline risk x RR 0.79 for corticosteroids = 13%). The control arm of the WHO SOLIDARITY trial, performed across a wide variety of countries and geographical regions, was identified by the GDG panel as generally representing the most relevant source of evidence for baseline risk estimates for mortality and mechanical ventilation for severely and critically ill patients with COVID-19.

2. Systematic review [6]. **Baseline/comparator:** Primary study. Baseline risk for mortality and mechanical ventilation were derived from the WHO SOLIDARITY trial for patients with severe and critical COVID-19, adjusted for corticosteroids as part of standard of care (16% baseline risk x RR 0.79 for corticosteroids = 13%). The control arm of the WHO SOLIDARITY trial, performed across a wide variety of countries and geographical regions, was identified by the GDG panel as generally representing the most relevant source of evidence for baseline risk estimates for mortality and mechanical ventilation for severely and critically ill patients with COVID-19.

3. Systematic review. **Baseline/comparator:** Control arm of reference used for intervention. We used the median event rate for all patients randomized to usual care across included studies. **Supporting references:** [6],

4. **Risk of Bias: serious.** We downgraded for some concerns regarding risk of bias due to lack of blinding and ascertainment

bias. **Imprecision: very serious.** We downgraded due to very wide confidence intervals crossing the null.

5. **Risk of Bias: serious.** We downgraded for some concerns regarding risk of bias due to lack of blinding and ascertainment bias. **Imprecision: serious.** Downgraded due to wide confidence intervals crossing the null.

6. **Risk of Bias: serious.** We downgraded for some concerns regarding risk of bias due to lack of blinding. **Imprecision: serious.** We downgraded as the lower limit of the confidence interval was close to the null.

7. **Risk of Bias: serious.** We downgraded for some concerns regarding risk of bias due to lack of blinding. **Inconsistency: serious.** Downgraded due to differences in point estimates and lack of overlap in confidence intervals.

### 7.3 Ivermectin (published 31 March 2021)

The fourth version of the WHO living guideline addressed the use of ivermectin in patients with COVID-19. It followed the increased international attention on ivermectin as a potential therapeutic option. While ivermectin is also being investigated for prophylaxis, the guideline only addressed its role in the treatment of COVID-19.

Ivermectin is relatively inexpensive and accessible, and some countries had already witnessed its widespread use in the treatment of COVID-19; in other countries, there was increasing pressure to do so (41). In response to this international attention, the WHO GDG provided recommendations on ivermectin for treatment of COVID-19.

#### Mechanism of action

Ivermectin is an antiparasitic agent that interferes with nerve and muscle function of helminths through binding glutamate-gated chloride channels (42). Based on in vitro experiments, some have postulated that ivermectin may have a direct antiviral effect against SARS-CoV-2. However, in humans the concentrations needed for in vitro inhibition are unlikely to be achieved by the doses proposed for COVID-19 (43)(44)(45). Ivermectin had no impact on SARS-CoV-2 viral RNA in the Syrian golden hamster model of SARS-CoV-2 infection (46). The proposed mechanism remains unclear: multiple targets have been proposed based upon either analogy to other viruses with very different life cycles, or, like several hundred other candidates, simulations indicating molecular docking with multiple viral targets including spike, RdRp and 3CLpro (47)(48)(49)(50)(51). No direct evidence for any mechanism of antiviral action against SARS-CoV-2 currently exists.

Some have proposed, based predominantly upon research in other indications, that ivermectin has an immunomodulatory effect, but again the mechanism remains unclear. Historical data showed that ivermectin improved survival in mice given a lethal dose of lipopolysaccharide (52), and has benefits in murine models of atopic dermatitis and allergic asthma (53)(54). For SARS-CoV-2, one hypothesis suggests immunomodulation mediated by allosteric modulation of the alpha-7 nicotinic acetylcholine receptor (indirectly by modulating the activity of ligands of the receptor). Although investigators have demonstrated this action in vitro, concentrations used in these experiments have been even higher than those required for an antiviral effect (55), and therefore very unlikely to be achieved in humans. In the Syrian golden hamster model of SARS-CoV-2 infection, ivermectin resulted in some changes in pulmonary immune phenotype consistent with allosteric modulation of the alpha-7 nicotinic acetylcholine receptor (46). However, ivermectin did not appear to rescue body weight loss which is a hallmark of disease in this model, and drug concentrations were not measured to extrapolate to those achieved in humans. Taken together, there remains great uncertainty regarding the relevance of any immunomodulatory or anti-inflammatory action of ivermectin.

#### Benefits and harms

The GDG members prioritized outcomes (rating from 1 [not important] to 9 [critical]) taking a patient's perspective. The panel prioritized outcomes from both an inpatient (same as for IL-6 inhibitor) and outpatient (Table 1) perspective. The panel's questions were structured using the PICO format (see evidence profile under the recommendations). These prioritized outcomes were used to update the LNMA.

#### Evidence summary

The evidence summary was based on 16 trials and 2407 participants for which the NMA provided relative estimates of effect for patient-important outcomes. Of the included trials, 75% examined patients with non-severe disease and 25% included both severe and non-severe patients. A number of the included trials did not report on our outcomes of interest. Of the trials, 25% were published in peer-reviewed journals, and 44% were available as preprints and 31% were completed but unpublished (See Table on trial characteristics). We excluded a number of quasi-RCTs (56)(57)(58)(59).

#### Subgroup analysis

The NMA team performed subgroup analyses which could result in distinct recommendations by subgroups. From the available data, subgroup analyses were only possible by dose of ivermectin and considering the outcomes of mortality, mechanical ventilation, admission to hospital, and adverse events leading to drug discontinuation. The ivermectin dose subgroup analyses were performed from the direct comparison of ivermectin versus usual care. For these analyses, meta-regression was used to evaluate the effect of cumulative dose as a continuous variable, and further adding a co-variate for single vs multiple dosing regimens. This approach was based on input from the pharmacology experts (led by Professor Andrew Owen) who performed pharmacokinetic simulations across trial doses, and found that cumulative ivermectin dose was expected to correlate with key pharmacokinetic parameters when single- and multiple-dose studies were segregated. It should be noted that the included trials did not directly assess the pharmacokinetics of ivermectin, and our approach was based upon simulations validated where possible against published pharmacokinetics in humans. The panel used a pre-specified framework incorporating the ICEMAN tool to assess the credibility of subgroup findings (24).

The GDG panel requested subgroup analyses based on: age (considering children vs younger adults vs older adults [70 years or older]); illness severity (non-severe vs severe vs critical COVID-19); time from onset of symptoms; and use of concomitant medications. However, there was insufficient within-trial data to perform any of these subgroup analyses, based on our pre-specified protocol. The panel recognized that usual care is likely variable between centres and regions, and has evolved over time. However, given all of the data come from RCTs, use of these co-interventions that comprise usual care should be balanced between study patients randomized to either the intervention or usual care arms.

**Baseline risk estimates** (prognosis of patients with COVID-19): informing absolute estimates of effect. The evidence summaries that informed the guideline recommendation reported the anticipated absolute effects of ivermectin compared with usual care across all patient-important outcomes. The absolute effects of treatment are informed by the prognosis (i.e. baseline risk estimates) combined with the relative estimates of effects (e.g. RR, OR) obtained from the NMA.

The control arm of the WHO SOLIDARITY trial (18), performed across a wide variety of countries and geographical regions, was identified by the GDG panel as generally representing the most relevant source of evidence for baseline risk estimates for mortality and mechanical ventilation. The rationale for selecting the WHO SOLIDARITY trial was to reflect the overall prognosis of the global population for which the WHO guideline recommendations are made. However, the SOLIDARITY trial only enrolls patients who are hospitalized with COVID-19. Since ivermectin has been proposed for use and often studied in outpatients, on this occasion the panel used the median of risk in the standard care arms of the included trials for baseline risk estimates for these outcomes. When applying the evidence to a particular patient or setting, for any medication with a convincing effect, clinicians should consider the individual's risk of mortality and need for mechanical ventilation. In view of the study designs, the GDG judged that for other outcomes using the median or mean of all patients randomized to usual care across the included studies would provide the most reliable estimate of baseline risk.

### Values and preferences

We had insufficient information to provide the GDG with a trustworthy description of patient experiences or values and preferences regarding treatment decisions for COVID-19 drug treatments. The GDG therefore relied on their own judgments of what well-informed patients would value after carefully balancing the benefits, harms and burdens of treatment. The GDG included four patient-partners who had lived experience with COVID-19.

The GDG agreed that the following values and preferences would be typical of well-informed patients:

- Most patients would be reluctant to use a medication for which the evidence left high uncertainty regarding effects on outcomes they consider important. This was particularly so when evidence suggested treatment effects, if they do exist, are small, and the possibility of important harm remains.
- In an alternative situation with larger benefits and less uncertainty regarding both benefits and harms, more patients would be inclined to choose the intervention.
- Although the GDG focused on an individual patient perspective, they also considered a population perspective in which feasibility, acceptability, equity and cost are important considerations.

**Info Box**

The recommendation concerning ivermectin was published on 31 March 2021 as the [fourth version](#) of the WHO living guideline and in the BMJ as [Rapid Recommendations](#). Please view the section text for a summary of the evidence requested to inform the recommendation.

No changes were made for the ivermectin recommendation in this sixth version of the guideline. We are aware of a few new, relatively small trials published since our recommendation was made and that one key trial has since been retracted given concerns about research fraud (60)(61). However the updated evidence summary from the LNMA is consistent with our previously made recommendation. This updated evidence summary will be fully considered by the GDG before the next iteration of this guideline.

**Only in research settings**

We recommend not to use ivermectin in patients with COVID-19 except in the context of a clinical trial.

*Remark: This recommendation applies to patients with any disease severity and any duration of symptoms.*

*A recommendation to only use a drug in the setting of clinical trials is appropriate when there is very low certainty evidence and future research has a large potential for reducing uncertainty about the effects of the intervention and for doing so at reasonable cost.*

**Practical Info**

The GDG made a recommendation against using ivermectin for treatment of patients with COVID-19 outside the setting of a clinical trial and therefore practical considerations are less relevant for this drug.

**Evidence To Decision****Benefits and harms**

The effects of ivermectin on mortality, mechanical ventilation, hospital admission, duration of hospitalization and viral clearance remain uncertain because of very low certainty of evidence addressing each of these outcomes. Ivermectin may have little or no effect on time to clinical improvement (low certainty evidence). Ivermectin may increase the risk of SAEs leading to drug discontinuation (low certainty evidence).

Subgroup analyses indicated no effect modification based on dose. We were unable to examine subgroups based on patient age or severity of illness due to insufficient trial data (see section text). Therefore, we assumed similar effects in all subgroups. This recommendation applies to patients with any disease severity and any duration of symptoms.

**Certainty of the Evidence**

For most key outcomes, including mortality, mechanical ventilation, hospital admission, duration of hospitalization and viral clearance, the GDG considered the evidence of very low certainty. Evidence was rated as very low certainty primarily because of very serious imprecision for most outcomes: the aggregate data had wide confidence intervals and/or very few events. There were also serious concerns related to risk of bias for some outcomes, specifically lack of blinding, lack of trial pre-registration, and lack of outcome reporting for one trial that did not report mechanical ventilation despite pre-specifying it in their protocol (publication bias).

For more details, see the Justification section for this recommendation. For other outcomes, including SAEs and time to clinical improvement, the certainty of the evidence was low.

**Preference and values**

Applying the agreed values and preferences (see Section 5), the GDG inferred that almost all well-informed patients would want to receive ivermectin only in the context of a randomized trial, given that the evidence left a very high degree of

uncertainty in effect on mortality, need for mechanical ventilation, need for hospitalization and other critical outcomes of interest and there was a possibility of harms, such as treatment-associated SAEs. The panel anticipated little variation in values and preferences between patients when it came to this intervention.

### Resources and other considerations

Ivermectin is a relatively inexpensive drug and is widely available, including in low-income settings. The low cost and wide availability do not, in the GDG's view, mandate the use of a drug in which any benefit remains very uncertain and ongoing concerns regarding harms remain. Although the cost may be low per patient, the GDG raised concerns about diverting attention and resources away from care likely to provide a benefit such as corticosteroids in patients with severe COVID-19 and other supportive care interventions. Also, use of ivermectin for COVID-19 would divert drug supply away from pathologies for which it is clearly indicated, potentially contributing to drug shortages, especially for helminth control and elimination programmes. Other endemic infections that may worsen with corticosteroids should be considered. If steroids are used in the treatment of COVID-19, empiric treatment with ivermectin may still be considered in Strongyloidiasis endemic areas, at the discretion of clinicians overseeing treatment, albeit not for treatment of COVID-19 itself.

### Justification

When moving from evidence to a recommendation on the use of ivermectin in patients with COVID-19 only in the context of a clinical trial, the GDG emphasized the high degree of uncertainty in the most critical outcomes such as mortality and need for mechanical ventilation. It also noted the evidence suggesting possible harm associated with treatment, with increased adverse events. The GDG did not anticipate important variability in patient values and preferences. Other contextual factors, such as resource considerations, accessibility, feasibility and impact on health equity did not alter the recommendation.

Compared with previous drugs evaluated as part of the WHO *Therapeutics and COVID-19: living guideline*, currently there are far fewer RCT data available for ivermectin. The existing data on ivermectin also have a substantially higher degree of uncertainty, with included trials having enrolled substantially fewer patients with far fewer events. Fig. 1 is the network map for mortality from the accompanying LNMA informing this guideline. Within the map, the size of the nodes (blue circles) correlates with the number of patients randomized to that intervention across all included trials; it is clear that the size of the ivermectin node is much smaller than other interventions which have been subjected to WHO guidelines, such as corticosteroids, hydroxychloroquine and lopinavir/ritonavir. The width of the line connecting two specific interventions correlates with the number of patients and number of events in this comparison across all trials; again, the lines connecting ivermectin to standard of care, as well as to the comparators lopinavir/ritonavir and hydroxychloroquine, are much thinner compared with drugs that have been assessed previously in this guideline.

**Figure 2. Network map from the living network meta-analysis informing this guideline**

**High degree of uncertainty**

The certainty in effect estimates for ivermectin on the main outcomes of interest, including mortality, is very low and therefore the effect of ivermectin on these outcomes remains uncertain. There are two domains that contribute to this uncertainty: serious risk of bias; and serious imprecision. Although 16 RCTs contributed to the evidence summary informing this drug, only five directly compared ivermectin with standard of care and reported mortality (62)(63)(64)(65)(66)(67)(68). Of note, and in keeping with our methodology, the LNMA team excluded quasi-randomized trials, or any RCT that did not use explicit randomization techniques. Of these five RCTs, two (62)(63) were at high risk of bias, due to inadequate blinding. One of these two trials (62) also started enrolling and randomizing patients prior to the protocol being publicly posted, another factor that contributes to an increased risk of bias. The potential impact of risk of bias is exemplified by subgroup analyses for mortality based on trial risk of bias. As demonstrated in the forest plot (Figure 3), the pooled estimate across all five RCTs that directly compare ivermectin with standard care suggests a reduction in mortality with ivermectin, but this effect is not apparent if we only consider the trials at low risk of bias (which together contribute nearly two-thirds of the evidence). This finding increases the degree of uncertainty regarding the true effect of ivermectin on mortality. Consistent with the direct evidence, a similar phenomenon is observed with the indirect evidence comparing ivermectin to standard of care (via comparisons against hydroxychloroquine and lopinavir/ritonavir). The indirect evidence suggesting a reduction in mortality with ivermectin is driven almost entirely by one study which is at high risk of bias (60) due to a lack of detailed description of blinding or randomization and the lack of a publicly available study protocol (figure not shown).

**Figure 3. Forest plot demonstrating direct comparison of ivermectin versus standard of care for mortality with subgroup analysis by risk of bias**

IV: inverse variance.

In addition to concerns related to risk of bias, for the outcome of mortality, there are very serious concerns related to imprecision. According to GRADE, imprecision is evaluated based on both a confidence interval approach and an evaluation of information size (event number), ensuring there is adequate information on which to make informed judgments (69). In this case, despite confidence intervals that suggest benefit with ivermectin, the information size is very low. For mortality (and ignoring the concerns related to risk of bias discussed above), there were nine deaths across all 511 patients randomized to ivermectin (1.76%) and 22 deaths across all 404 patients randomized to standard of care (5.45%). This is an extremely small number of events on which to base conclusions, and far below the optimal information size. In fact, performing a theoretical exercise in which a change of three events (deaths) is made from those randomized to standard of care to those randomized to ivermectin eliminates any statistical significance, a finding that suggests that results could reasonably be due to chance alone. Furthermore, the evidence informing this comparison is from multiple small trials, adding to the risk of unrecognized imbalances in study arms. Given the strong likelihood that chance may be playing a role in the observed findings, the panel believed there was very serious imprecision further lowering the overall certainty in findings.

This combination of serious risk of bias and very serious imprecision contributed to very low certainty of evidence for mortality despite a point estimate and confidence interval that appear to suggest benefit with ivermectin. As a result, the panel concluded that the effect of ivermectin on mortality is uncertain. Similar considerations were applied to the other critical outcomes including mechanical ventilation, hospital admission, and duration of hospitalization and resulted in very low certainty for these outcomes as well.

### Subgroup analyses

We conducted subgroup analysis only for effect by ivermectin dose and the panel did not find any evidence of a subgroup effect (see section text). A lack of within-trial comparisons prevented subgroup analyses by age or disease severity. Therefore, the panel did not make any subgroup recommendation for this drug. In other words, the recommendation against ivermectin except in the context of clinical trials is applicable across disease severity, age groups, and all dose regimens of ivermectin.

### Applicability

None of the included RCTs enrolled children under 15, and therefore the applicability of this recommendation to children is currently uncertain. However, the panel had no reason to think that children with COVID-19 would respond any differently to treatment with ivermectin. There were similar considerations for pregnant women, with no data directly examining this population, but no rationale to suggest they would respond differently to other adults.

### Uncertainties

Please see end of document for residual uncertainties (Section 8).

## Clinical Question/ PICO

<b>Population:</b>	Patients with COVID-19 infection (all disease severities)
<b>Intervention:</b>	Ivermectin
<b>Comparator:</b>	Usual care

Outcome Timeframe	Study results and measurements	Comparator Standard care	Intervention Ivermectin	Certainty of the Evidence (Quality of evidence)	Plain language summary
Mortality	Odds Ratio 0.19 (CI 95% 0.09 – 0.36) Based on data from 1,419 patients in 7 studies. <sup>1</sup> (Randomized controlled)	<b>70</b> per 1000  Difference:	<b>14</b> per 1000  <b>56 fewer per 1000</b> ( CI 95% 63 fewer – 44 fewer )	<b>Very low</b> Due to serious risk of bias and very serious imprecision <sup>2</sup>	The effect of ivermectin on mortality is uncertain.
Mechanical ventilation	Odds Ratio 0.51 (CI 95% 0.12 – 1.77) Based on data from 687 patients in 5 studies. (Randomized controlled)	<b>20</b> per 1000  Difference:	<b>10</b> per 1000  <b>10 fewer per 1000</b> ( CI 95% 18 fewer – 15 more )	<b>Very low</b> Due to very serious imprecision and publication bias <sup>3</sup>	The effect of ivermectin on mechanical ventilation is uncertain.
Viral clearance 7 days	Odds Ratio 1.62 (CI 95% 0.95 – 2.86) Based on data from 625 patients in 6 studies. (Randomized controlled)	<b>500</b> per 1000  Difference:	<b>618</b> per 1000  <b>118 more per 1000</b> ( CI 95% 13 fewer – 241 more )	<b>Low</b> Due to serious inconsistency and imprecision <sup>4</sup>	Ivermectin may increase or have no effect on viral clearance.
Hospital admission (outpatients only)	Odds Ratio 0.36 (CI 95% 0.08 – 1.48) Based on data from 398 patients in 1 studies. (Randomized controlled)	<b>50</b> per 1000  Difference:	<b>18</b> per 1000  <b>32 fewer per 1000</b> ( CI 95% 47 fewer – 23 more )	<b>Very low</b> Due to extreme imprecision <sup>5</sup>	The effect of ivermectin on hospital admission is uncertain.
Serious adverse events	Odds Ratio 3.07 (CI 95% 0.77 – 12.09) Based on data from 584 patients in 3 studies. (Randomized controlled)	<b>9</b> per 1000  Difference:	<b>27</b> per 1000  <b>18 more per 1000</b> ( CI 95% 2 fewer – 89 more )	<b>Low</b> Due to very serious imprecision <sup>6</sup>	Ivermectin may increase the risk of serious adverse events leading to drug discontinuation.
Time to clinical improvement	Measured by: days Lower better Based on data from: 633 patients in 2 studies. (Randomized controlled)	<b>11</b> days (Mean)  Difference:	<b>10.5</b> days (Mean)  <b>MD 0.5 fewer</b> ( CI 95% 1.7 fewer – 1.1 more )	<b>Low</b> Due to very serious imprecision <sup>7</sup>	Ivermectin may have little or no difference on time to clinical improvement
Duration of hospitalization	Measured by: days Lower better Based on data from: 252 patients in 3 studies. (Randomized controlled)	<b>12.8</b> days (Mean)  Difference:	<b>11.7</b> days (Mean)  <b>MD 1.1 fewer</b>	<b>Very low</b> Due to serious imprecision, inconsistency and serious risk of bias	The effect of ivermectin on hospital length of stay is uncertain.

Outcome Timeframe	Study results and measurements	Comparator Standard care	Intervention Ivermectin	Certainty of the Evidence (Quality of evidence)	Plain language summary
Time to viral clearance	Measured by: days Lower better Based on data from: 559 patients in 4 studies. (Randomized controlled)	7.3 days (Mean)  Difference:	( CI 95% 2.3 fewer – 0.1 more )  5.7 days (Mean)  MD 1.6 fewer ( CI 95% 4.1 fewer – 3 more )	8  Very low Due to very serious imprecision and serious risk of bias. <sup>9</sup>	We are uncertain whether ivermectin improves or worsen time to viral clearance

1. Systematic review [5]. **Baseline/comparator:** Control arm of reference used for intervention. We elected to use the control arm of the WHO solidarity trial, reflecting usual care across countries participating in the trial.
2. **Risk of Bias: serious.** The large trial contributing most of the effect estimate was driven by studies that were not blinded.. **Inconsistency: no serious. Indirectness: no serious. Imprecision: very serious.** The number of total events was very small.. **Publication bias: no serious.**
3. **Inconsistency: no serious. Indirectness: no serious. Imprecision: very serious.** Very few events and credible intervals that include both important benefit and harm.. **Publication bias: serious.**
4. **Inconsistency: serious.** The point estimates varied widely and credible intervals do not substantially overlap.. **Indirectness: no serious. Imprecision: serious.** Credible interval includes no effect.. **Publication bias: no serious.**
5. **Inconsistency: no serious. Indirectness: no serious. Imprecision: very serious.** Credible interval includes important benefit and harm.. **Publication bias: no serious.**
6. **Inconsistency: no serious. Indirectness: no serious. Imprecision: serious.** Credible interval includes little to no difference.. **Publication bias: no serious.**
7. **Inconsistency: no serious. Indirectness: no serious. Imprecision: very serious. Publication bias: no serious.**
8. **Risk of Bias: serious.** Result driven by one study that was not blinded.. **Inconsistency: serious.** Despite overlapping confidence intervals, point estimates discrepant.. **Indirectness: no serious. Imprecision: serious.** Credible intervals include no difference.. **Publication bias: no serious.**
9. **Risk of Bias: serious.** Concerns around risk of bias.. **Inconsistency: no serious. Indirectness: no serious. Imprecision: very serious.** Credible interval includes important benefit and important harm.. **Publication bias: no serious.**

## 7.4 Hydroxychloroquine (published 17 December 2020)

The third version of the WHO living guideline addressed the use of hydroxychloroquine (and lopinavir/ritonavir) in patients with COVID-19. It followed the pre-print publication of the WHO SOLIDARITY trial on 15 October, 2020, reporting results on treatment with remdesivir, hydroxychloroquine and lopinavir/ritonavir in hospitalized patients with COVID-19 (18). The role of these drugs in clinical practice has remained uncertain, with limited prior trial evidence. The WHO SOLIDARITY trial adds 11 266 randomized patients (2570 to remdesivir, 954 to hydroxychloroquine, and 1411 to lopinavir/ritonavir, 6331 to usual care) and had the potential to change practice (17)(18).

### The evidence

The evidence summary for hydroxychloroquine was based on 30 trials and 10 921 participants for which the NMA provided relative estimates of effect for patient-important outcomes (Table 2). Five of the trials (414 total participants) randomized some patients to chloroquine.

**Table 4. Summary of trials and trial characteristics informing the hydroxychloroquine recommendation**  
(trials = 30, total patients = 10 921)

Geographic region	Region of the Americas	Region of the Americas
-------------------	------------------------	------------------------

	South-East Asia Region Western Pacific Region  European Region  Eastern Mediterranean Region	(12 trials, 2358 patients) South-East Asea and Western Pacific Regions (7 trials, 731 patients) European Region (10 trials, 7638 patients) Eastern Mediterranean Region (1 trial, 194 patients)
<b>Severity of illness<sup>a</sup></b>	Non-severe  Severe  Critically ill	Mild/Moderate (10 trials, 2436 patients) Severe (1 trial, 479 patients) Critically ill (0 trials, 0 patients)
<b>Mechanically ventilated at baseline<sup>b</sup></b>	Mean (range), %	3.23 (0-16.8)
<b>Age<sup>c</sup></b>	Mean (range of means), years	50.8 (32.9-77)
<b>Sex<sup>d</sup></b>	Mean (range of means), % women	46.9 (30-71)
<b>Loading doses Day 1<sup>e</sup></b>	Mean (range of means), mg	1010 (800-1600)
<b>Total cumulative doses<sup>f</sup></b>	Mean (range), mg	4000 (2000-11 200)
<b>Duration of therapy<sup>g</sup></b>	Median (range), days	7 (4-16)
<b>Type of care</b>	n (%) inpatient  n (%) outpatient	Inpatient: 9549 (87.4)  Outpatient: 1372 (12.6)
<b>Trial participants</b>	Median (range)	364 (2-4716)
<b>Concomitant use of corticosteroids<sup>h</sup></b>	Mean (range across trials that report this), %	12.61 (8-19.5)

**Notes:**

<sup>a</sup> 19 trials did not report the disease severity of patients.

<sup>b</sup> 19 trials did not report the proportion of mechanical ventilation at baseline.

<sup>c</sup> Based on 15 trials and 8006 patients. For the other 15 trials: 1 trial did not report the age of patients, and the other 14 trials reported that the age of patients were  $\geq 12$ , 18, or 40.

<sup>d</sup> 14 trials did not report the sex of patients.

<sup>e</sup> 10 trials did not use a loading dose.

<sup>f</sup> 1 trial reported range of treatment duration.

<sup>g</sup> 1 trial reported range of treatment duration.

<sup>h</sup> 23 trials did not report the concomitant use of corticosteroids.

**Baseline risk**

The absolute effects of treatment are informed by the prognosis (i.e. baseline risk estimates) combined with the relative estimates of effects (e.g. RR, OR) obtained from the NMA.

The control arm of the WHO SOLIDARITY Trial (18), performed across a wide variety of countries and geographical regions, was identified by the GDG panel as representing the most relevant source of evidence to make the baseline risk estimates for the outcomes of mortality and mechanical ventilation. The rationale for selecting the WHO SOLIDARITY Trial was to reflect the overall prognosis of the global population for which the WHO guideline recommendations are made. When applying the evidence to a particular patient or setting, the individual or setting's risk of mortality and mechanical ventilation should be considered. In view of the study designs, the GDG determined that for other outcomes using the median or mean of all patients randomized to usual care across the included studies would provide the most reliable estimate of baseline risk.

### Subgroup analysis

For hydroxychloroquine, the GDG panel requested subgroup analyses based on age (considering children vs younger adults [e.g. under 70 years] vs older adults [e.g. 70 years or older]), illness severity (non-severe vs severe vs critical COVID-19) and based on whether or not it was co-administered with azithromycin.

The panel also requested a subgroup analysis based on high dose vs low dose hydroxychloroquine. A categorical approach to hydroxychloroquine dosing proved impossible because the trials used varying loading doses, continuation doses and durations. Therefore, in collaboration with a pharmacology expert (Professor Andrew Owen), we modelled the expected serum concentrations over time. We hypothesized that higher trough concentrations early in the treatment course (e.g. trough concentration on Day 3) might be more effective than lower early trough concentrations. We also hypothesized that higher maximum serum concentrations (e.g. peak concentration on the last day) might result in higher risk of adverse effects than lower maximum serum concentrations. In our pharmacokinetic model, the cumulative dose was highly correlated with all measures of serum concentrations on Day 3 and the final day of treatment, and therefore we decided to use cumulative dose as the primary analysis. Day 3 trough concentration was least strongly correlated with total cumulative dose ( $R^2 = 0.376$ ) and therefore we performed a sensitivity subgroup analysis with predicted Day 3 trough concentrations for efficacy outcomes.

#### Info Box

The recommendation concerning hydroxychloroquine was published 17 December 2020 as the [third version](#) of the WHO living guideline and in the BMJ as [Rapid Recommendations](#). No changes were made for the hydroxychloroquine recommendation in this sixth version of the guideline. Please view the section text for a summary of the evidence requested to inform the recommendation, triggered by the WHO SOLIDARITY trial.

#### Recommendation against

We recommend against administering hydroxychloroquine or chloroquine for treatment of COVID-19.

*Remark: This recommendation applies to patients with any disease severity and any duration of symptoms.*

### Practical Info

The GDG made a strong recommendation against using hydroxychloroquine or chloroquine for treatment of patients with COVID-19. The use of hydroxychloroquine may preclude the use of other important drugs that also prolong the QT interval, such as azithromycin and fluoroquinolones. Concomitant use of drugs that prolong the QT interval should be done with extreme caution.

### Evidence To Decision

#### Benefits and harms

Hydroxychloroquine and chloroquine probably do not reduce mortality or mechanical ventilation and may not reduce duration of hospitalization. The evidence does not exclude the potential for a small increased risk of death and mechanical ventilation with hydroxychloroquine. The effect on other less important outcomes, including time to symptom resolution, admission to hospital, and duration of mechanical ventilation, remains uncertain.

Hydroxychloroquine may increase the risk of diarrhoea and nausea/vomiting; a finding consistent with evidence from its use in other conditions. Diarrhoea and vomiting may increase the risk of hypovolaemia, hypotension and acute kidney injury, especially in settings where health care resources are limited. Whether or not and to what degree hydroxychloroquine

increases the risk of cardiac toxicity, including life-threatening arrhythmias, is uncertain.

Subgroup analyses indicated no effect modification based on severity of illness (comparing either critical vs severe/non-severe or non-severe vs critical/severe) or age (comparing those aged less than 70 years versus those aged 70 years and older). Further, the cumulative dose and predicted Day 3 serum trough concentrations did not modify the effect for any outcome. Therefore, we assumed similar effects in all subgroups.

We also reviewed evidence comparing the use of hydroxychloroquine plus azithromycin vs hydroxychloroquine alone. There was no evidence that the addition of azithromycin modified the effect of hydroxychloroquine for any outcome (very low certainty).

### **Certainty of the Evidence**

For the key outcomes of mortality and mechanical ventilation, the panel considered the evidence to be of moderate certainty. There were residual concerns about lack of blinding in the largest trials and the imprecision. For example, the credible interval around the pooled effect leaves open the possibility of a very small reduction in mortality. The quality of evidence was low for diarrhoea and nausea/vomiting because of lack of blinding in many of the trials and because the total number of patients enrolled in trials reporting these outcomes was smaller than the optimal information size (although the credible interval laid entirely on the side of harm for both outcomes).

For all other outcomes, the certainty of the evidence was low or very low. The primary concerns with the data were imprecision (credible intervals included both important benefit and important harm) as well as risk of bias (lack of blinding).

### **Preference and values**

Applying the agreed values and preferences (see Evidence section above), the GDG inferred that almost all well-informed patients would not want to receive hydroxychloroquine given the evidence suggesting there was probably no effect on mortality or need for mechanical ventilation and there was a risk of adverse events including diarrhoea and nausea and vomiting. The panel did not expect there would be much variation in values and preferences between patients when it came to this intervention.

### **Resources and other considerations**

Hydroxychloroquine and chloroquine are relatively inexpensive compared with other drugs used for COVID-19 and are already widely available, including in low-income settings. Despite this, the panel felt that almost all patients would choose not to use hydroxychloroquine or chloroquine because the harms outweigh the benefits. Although the cost may be low per patient, the GDG panel raised concerns about diverting attention and resources away from care likely to provide a benefit such as corticosteroids in patients with severe COVID-19 and other supportive care interventions.

## **Justification**

When moving from evidence to the strong recommendation against the use of hydroxychloroquine or chloroquine for patients with COVID-19, the panel emphasized the moderate certainty evidence of probably no reduction in mortality or need for mechanical ventilation. It also noted the evidence suggesting possible harm associated with treatment, with increased nausea and diarrhoea. The GDG did not anticipate important variability in patient values and preferences, and other contextual factors, such as resource considerations, accessibility, feasibility and impact on health equity (see summary of these factors under Evidence to decision).

### **Subgroup analyses**

The panel did not find any evidence of a subgroup effect across patients with different levels of disease severity, between adults and older adults, and by different doses, and therefore did not make any subgroup recommendation for this drug. In other words, the strong recommendation is applicable across disease severity, age groups, and all doses and dose schedules of hydroxychloroquine.

The trials included patients from around the world, with all disease severities, and treated in different settings (outpatient and inpatient). Although the trials did not report subgroup effects by time from symptom onset, many of the trials enrolled patients

early in the disease course. The GDG panel therefore felt that the evidence applies to all patients with COVID-19.

**Applicability**

*Special populations*

None of the included RCTs enrolled children, and therefore the applicability of this recommendation to children is currently uncertain. However, the panel had no reason to think that children with COVID-19 would respond any differently to treatment with hydroxychloroquine. There were similar considerations in regards to pregnant women, with no data directly examining this population, but no rationale to suggest they would respond differently than other adults. Hydroxychloroquine crosses the placental barrier and there are concerns that it may lead to retinal damage in neonates. Although hydroxychloroquine has been used in pregnant women with systemic autoimmune diseases, such as systemic lupus erythematosus, pregnant women may have even more reasons than other patients to be reluctant to use hydroxychloroquine for COVID-19.

*In combination with azithromycin*

There was no evidence from the NMA that the addition of azithromycin modified the effect of hydroxychloroquine for any outcome. As there were no trial data suggesting that azithromycin favourably modifies the effect of hydroxychloroquine, the recommendation against hydroxychloroquine and chloroquine applies to patients whether or not they are concomitantly receiving azithromycin.

**Uncertainties**

Please see end of document for residual uncertainties (Section 8). The GDG panel felt that it was unlikely future studies would identify a subgroup of patients that are likely to benefit from hydroxychloroquine or chloroquine.

**Clinical Question/ PICO**

- Population:** Patients with COVID-19 infection (all disease severities)
- Intervention:** Hydroxychloroquine + usual care
- Comparator:** Usual care

Outcome Timeframe	Study results and measurements	Comparator Standard care	Intervention Hydroxychloro quine	Certainty of the Evidence (Quality of evidence)	Plain language summary
Mortality	Odds Ratio 1.11 (CI 95% 0.95 – 1.31) Based on data from 10,859 patients in 29 studies. <sup>1</sup> (Randomized controlled)	<b>106</b> per 1000  Difference:	<b>116</b> per 1000  <b>10 more per 1000</b> ( CI 95% 5 fewer – 28 more )	<b>Moderate</b> Due to borderline risk of bias and imprecision <sup>2</sup>	Hydroxychloroquine probably does not reduce mortality.
Mechanical ventilation	Odds Ratio 1.2 (CI 95% 0.83 – 1.81) Based on data from 6,379 patients in 5 studies. (Randomized controlled)	<b>105</b> per 1000  Difference:	<b>123</b> per 1000  <b>18 more per 1000</b> ( CI 95% 16 fewer – 70 more )	<b>Moderate</b> Due to borderline risk of bias and serious imprecision <sup>3</sup>	Hydroxychloroquine probably does not reduce mechanical ventilation.
Viral clearance 7 days	Odds Ratio 1.08 (CI 95% 0.25 – 4.78) Based on data from 280 patients in 4 studies. <sup>4</sup> (Randomized controlled)	<b>483</b> per 1000  Difference:	<b>502</b> per 1000  <b>19 more per 1000</b> ( CI 95% 294 fewer – 334 more )	<b>Very low</b> Due to very serious imprecision <sup>5</sup>	The effect of hydroxychloroquine on viral clearance is very uncertain.

Outcome Timeframe	Study results and measurements	Comparator Standard care	Intervention Hydroxychloro quine	Certainty of the Evidence (Quality of evidence)	Plain language summary
Admission to hospital	Odds Ratio 0.39 (CI 95% 0.12 – 1.28) Based on data from 465 patients in 1 studies. 13. **Risk of Bias: serious. Imprecision: very serious.**
14. **Imprecision: very serious.**

## 7.5 Lopinavir/ritonavir (published 17 December 2020)

The third version of the WHO living guideline addressed the use of lopinavir/ritonavir (and hydroxychloroquine, see above) in patients with COVID-19. It followed the pre-print publication of the WHO SOLIDARITY trial on 15 October 2020, reporting results on treatment with remdesivir, hydroxychloroquine and lopinavir/ritonavir in hospitalized patients with COVID-19 (18). The role of these drugs in clinical practice has remained uncertain, with limited prior trial evidence. The WHO SOLIDARITY trial adds 11 266 randomized patients (2570 to remdesivir, 954 to hydroxychloroquine, and 1411 to lopinavir/ritonavir, 6331 to usual care) and had the potential to change practice (17)(18).

### The evidence

For lopinavir/ritonavir, the evidence summary was based on 7 trials with 7429 participants. Of note, none of the included studies enrolled children or adolescents under the age of 19 years old (Table 5).

**Table 5. Summary of trials and trial characteristics informing the lopinavir/ritonavir recommendation**

(trials = 7, total patients = 7429)

<b>Geographic region</b>	Region of the Americas	Region of the Americas (0 trials, 0 patients)
	South-East Asia Region	South-East Asia and Western Pacific Regions (5 trials, 535 patients)
	Western Pacific Region	
	European Region	European Region (2 trials, 6894 patients)
	Eastern Mediterranean Region	Middle East (0 trial, 0 patients)
<b>Severity of illness<sup>a</sup></b>	Non-severe	Mild/Moderate (4 trials, 336 patients)
	Severe	Severe (1 trial, 199 patients)
	Critically ill	Critically ill (0 trials, 0 patients)

NR: Not reported.

**Notes:**<sup>a</sup> 2 trials did not report the disease severity of patients.<sup>b</sup> 3 trials did not report the proportion of mechanical ventilation at baseline.<sup>c</sup> 2 trials did not report the age of patients.<sup>d</sup> No trial reported loading dose.<sup>e</sup> 1 trial did not report cumulative doses; 2 trials only reported range of treatment duration.<sup>f</sup> 1 trial did not report the duration of therapy; 2 trials used a range of treatment duration.<sup>g</sup> 2 trials did not report the concomitant use of corticosteroids.**Baseline risk**

The absolute effects of treatment are informed by the prognosis (i.e. baseline risk estimates) combined with the relative estimates of effects (e.g. RR, OR) obtained from the NMA.

The control arm of the WHO SOLIDARITY trial (18), performed across a wide variety of countries and geographical regions, was identified by the GDG panel as representing the most relevant source of evidence to make the baseline risk estimates for the outcomes of mortality and mechanical ventilation. The rationale for selecting the WHO SOLIDARITY trial was to reflect the overall prognosis of the global population for which the WHO guideline recommendations are made. When applying the evidence to a particular patient or setting, the individual or setting's risk of mortality and mechanical ventilation should be considered. In view of the study designs, the GDG determined that for other outcomes using the median or mean of all patients randomized to usual care across the included studies would provide the most reliable estimate of baseline risk.

### Subgroup analysis

For lopinavir/ritonavir, the GDG panel requested subgroup analyses based on age (considering children vs younger adults [e.g. under 70 years] vs older adults [e.g. 70 years or older]), and illness severity (non-severe vs severe vs critical COVID-19). The GDG discussed other potential subgroups of interest including time from onset of symptoms until initiation of therapy and concomitant medications, but recognized that these analyses would not be possible without access to individual participant data and/or more detailed reporting from the individual trials.

#### Info Box

The recommendation concerning lopinavir/ritonavir was published 17 December 2020 as the [third version](#) of the WHO living guideline and in the BMJ as [Rapid Recommendations](#). No changes were made for the lopinavir/ritonavir recommendation in this sixth version of the guideline. Please view the section text for a summary of the evidence requested to inform the recommendation, triggered by the WHO SOLIDARITY trial.

#### Recommendation against

We recommend against administering lopinavir/ritonavir for treatment of COVID-19.

*Remark: This recommendation applies to patients with any disease severity and any duration of symptoms.*

### Evidence To Decision

#### Benefits and harms

The GDG panel found a lack of evidence that lopinavir/ritonavir improved outcomes that matter to patients such as reduced mortality, need for mechanical ventilation, time to clinical improvement and others. For mortality and need for mechanical ventilation this was based on moderate certainty evidence, for the other outcomes low or very low certainty evidence.

There was low certainty evidence that lopinavir/ritonavir may increase the risk of diarrhoea and nausea and vomiting, a finding consistent with the indirect evidence evaluating its use in patients with HIV. Diarrhoea and vomiting may increase the risk of hypovolaemia, hypotension and acute kidney injury, especially in settings where health care resources are limited. There was an uncertain effect on viral clearance and acute kidney injury.

Subgroup analysis indicated no effect modification based on severity of illness (comparing either critical vs severe/non-severe or non-severe vs critical/severe) or age (comparing those aged < 70 years versus those 70 years and older). As there was no evidence of a statistical subgroup effect, we did not formally evaluate using the ICEMAN tool.

#### Certainty of the Evidence

The evidence is based on a linked systematic review and NMA of seven RCTs; pooling data from 7429 patients hospitalized with various severities of COVID-19 and variably reporting the outcomes of interest to the guideline panel (5). The panel agreed that there was moderate certainty for mortality and need for mechanical ventilation, low certainty for diarrhoea, nausea and duration of hospitalization and very low certainty in the estimates of effect for viral clearance, acute kidney injury and time to clinical improvement. Most outcomes were lowered for risk of bias and imprecision (wide confidence

intervals which do not exclude important benefit or harm).

### Preference and values

Applying the agreed values and preferences (see Evidence section above), the GDG inferred that almost all well-informed patients would not want to receive lopinavir/ritonavir given the evidence suggested there was probably no effect on mortality or need for mechanical ventilation and there was a risk of adverse events including diarrhoea and nausea and vomiting. The panel did not expect there would be much variation in values and preferences between patients when it came to this intervention.

### Resources and other considerations

Although the cost of lopinavir/ritonavir is not as high as some other investigational drugs for COVID-19, and the drug is generally available in most health care settings, the GDG raised concerns about opportunity costs and the importance of not drawing attention and resources away from best supportive care or the use of corticosteroids in severe COVID-19.

## Justification

When moving from evidence to the strong recommendation against the use of lopinavir/ritonavir for patients with COVID-19, the panel emphasized the moderate certainty evidence of probably no reduction in mortality or need for mechanical ventilation. It also noted the evidence suggesting possible harm associated with treatment, with increased nausea and diarrhoea. The GDG did not anticipate important variability in patient values and preferences, and other contextual factors, such as resource considerations, accessibility, feasibility and impact on health equity would not alter the recommendation (see summary of these factors under Evidence to decision).

### Subgroup analysis

The panel did not find any evidence of a subgroup effect across patients with different levels of disease severity, or between adults and older adults and therefore did not make any subgroup recommendation for this drug. Although the trials did not report subgroup effects by time from symptom onset, many of the trials enrolled patients with patients early in the disease course. The strong recommendation is applicable across disease severity and age groups.

### Applicability

None of the included RCTs enrolled children, and therefore the applicability of this recommendation to children is currently uncertain. However, the panel had no reason to think that children with COVID-19 would respond any differently to treatment with lopinavir/ritonavir. There were similar considerations in regards to pregnant women, with no data directly examining this population, but no rationale to suggest they would respond differently than other adults. In patients using lopinavir/ritonavir for HIV infection, it should generally be continued while receiving care for COVID-19.

### Uncertainties

Please see end of document for residual uncertainties (Section 8). The GDG panel felt that it was unlikely future studies would identify a subgroup of patients that are likely to benefit from lopinavir/ritonavir.

### Additional considerations

In patients who have undiagnosed or untreated HIV, use of lopinavir/ritonavir alone may promote HIV resistance to important antiretrovirals. Widespread use of lopinavir/ritonavir for COVID-19 may cause drug shortages for people living with HIV.

---

## Clinical Question/ PICO

<b>Population:</b>	Patients with COVID-19 (all disease severities)
<b>Intervention:</b>	Lopinavir/ritonavir
<b>Comparator:</b>	Standard care

Outcome Timeframe	Study results and measurements	Comparator Standard care	Intervention Lopinavir/ ritonavir	Certainty of the Evidence (Quality of evidence)	Plain language summary
Mortality	Odds Ratio 1 (CI 95% 0.82 – 1.2) Based on data from 8,061 patients in 4 studies. <sup>1</sup> (Randomized controlled)	<b>106</b> per 1000  Difference:	<b>106</b> per 1000  <b>0 fewer per 1000</b> ( CI 95% 17 fewer – 19 more )	<b>Moderate</b> Due to borderline risk of bias and imprecision <sup>2</sup>	Lopinavir/ritonavir probably has no effect on mortality
Mechanical ventilation	Relative risk 1.16 (CI 95% 0.98 – 1.36) Based on data from 7,579 patients in 3 studies. (Randomized controlled)	<b>105</b> per 1000  Difference:	<b>122</b> per 1000  <b>17 more per 1000</b> ( CI 95% 2 fewer – 38 more )	<b>Moderate</b> Due to borderline risk of bias and imprecision <sup>3</sup>	Lopinavir/ritonavir probably does not reduce mechanical ventilation
Viral clearance	Odds Ratio 0.35 (CI 95% 0.04 – 1.97) Based on data from 171 patients in 2 studies. <sup>4</sup> (Randomized controlled)	<b>483</b> per 1000  Difference:	<b>246</b> per 1000  <b>237 fewer per 1000</b> ( CI 95% 447 fewer – 165 more )	<b>Low</b> Due to very serious imprecision <sup>5</sup>	the effects of lopinavir/ ritonavir on viral clearance is very uncertain

1. Systematic review. **Baseline/comparator:** Primary study[18]. Baseline risk for mortality and mechanical ventilation were derived from the WHO SOLIDARITY trial for patients with severe and critical COVID-19. **Supporting references:** [5],
2. **Imprecision: serious.** The 95% CI crosses the minimally important difference (2% reduction in mortality).
3. **Imprecision: serious.** Wide confidence intervals.
4. Systematic review. **Baseline/comparator:** Control arm of reference used for intervention. We used the median event rate for all patients randomized to usual care across included studies. **Supporting references:** [5],
5. **Imprecision: very serious.** Wide confidence intervals.
6. **Risk of Bias: serious. Imprecision: very serious.** Wide confidence intervals.
7. **Risk of Bias: serious.** Concerns mitigated because of large effect and indirect evidence showing consistent results. **Imprecision: serious.** Few patients and events. **Upgrade: large magnitude of effect.**
8. **Risk of Bias: serious.** Concerns mitigated because of large effect and indirect evidence showing consistent results. **Imprecision: serious.** Few patients and events. **Upgrade: large magnitude of effect.**
9. **Risk of Bias: serious. Imprecision: very serious.** Wide confidence intervals, low number of patients.
10. **Risk of Bias: serious. Imprecision: serious.** Wide confidence intervals.

## 7.6 Remdesivir (published 20 November 2020)

The second version of the WHO living guideline addressed the use of remdesivir in patients with COVID-19. It followed the pre-print publication of the WHO SOLIDARITY trial on 15 October 2020, reporting results on treatment with remdesivir, hydroxychloroquine and lopinavir/ritonavir in hospitalized patients with COVID-19 (18). The role of these drugs in clinical practice has remained uncertain, with limited prior trial evidence. The WHO SOLIDARITY trial adds 11 266 randomized patients (2570 to remdesivir, 954 to hydroxychloroquine, and 1411 to lopinavir/ritonavir, 6331 to usual care) and had the potential to change practice (17)(18).

The WHO GDG started with developing trustworthy recommendations on remdesivir, followed by the now published recommendations on hydroxychloroquine and lopinavir/ritonavir in the third update. Remdesivir is a novel monophosphoramidate adenosine analogue prodrug which is metabolized to an active tri-phosphate form that inhibits viral RNA synthesis. Remdesivir has in vitro and in vivo antiviral activity against several viruses, including SARS-CoV-2. Remdesivir is widely used in many countries, with several guidelines recommending its use in patients with severe or critical COVID-19 (70)(71).

### The evidence

The GDG panel requested an update of the living NMA of RCTs of drug treatments for COVID-19, based around important clinical questions to be addressed in the recommendations. The rating of importance of outcomes, selection of estimates for baseline risk and considerations about values and preferences were similar to what is presented in Section 5.

Based on 4 trials with 7333 participants (18)(72)(73)(74), the NMA provided relative estimates of effect for patient-important outcomes (Table below). Of note, none of the included studies enrolled children or adolescents under the age of 19 years old.

Table 6. Summary of trials and trial characteristics informing the remdesivir recommendation

Study	n	Location	Mean age (years)	Severity (% as per WHO criteria)	% IMV (at baseline)	Treatments (dose and duration)	Outcomes
Beigel (ACTT-1)	1063	United States, Europe, Asia	58.9	Non-severe (11.3) Severe <sup>a</sup> (88.7)	44.1	Remdesivir IV (100 mg/day for 10 days)	- Mortality - Adverse effects - Time to clinical improvement
Spinner (SIMPLE MODERATE*)	596	United States, Europe, Asia	56-58	Non-severe (100)	0	Remdesivir IV (200 mg at day 1, then 100 mg for 4 days or 9 days)	- Mortality - Mechanical ventilation - Adverse effects - Duration of hospitalization - Time to clinical improvement
Pan (SOLIDARITY)	5451	Worldwide	< 50: 35% 50-70: 47% >70: 18%	Non-severe (24) Severe <sup>b</sup> (67) Critical (9)	8.9	Remdesivir IV (200 mg at day 1, then 100 mg day 2-10)	- Mortality - Mechanical ventilation
Wang	237	China	65	Severe <sup>c</sup> (100)	16.1	Remdesivir IV (100 mg/day for 10 days)	- Mortality - Mechanical ventilation - Duration of ventilation - Adverse effects - Duration of hospitalization - Time to clinical improvement - Viral clearance

IMV: invasive mechanical ventilation; IV: intravenous; n: number.

#### Notes:

Severity criteria based on WHO definitions unless otherwise stated:

a: defined severe as SpO<sub>2</sub> < 94% on room air OR respiratory rate > 24 breaths per minute.

b: defined severe as requiring oxygen support.

c: defined severe as SpO<sub>2</sub> < 94% on room air.

\*Only SIMPLE MODERATE was included in the analysis, as SIMPLE SEVERE did not have a placebo/usual care arm.

#### Subgroup analysis

The GDG panel requested subgroup analyses based on age (considering children vs adults vs older people), illness severity (non-severe vs severe vs critical COVID), and duration of remdesivir therapy (5 days vs longer than 5 days). The GDG discussed other potential subgroups of interest including time from onset of symptoms until initiation of therapy, and concomitant medications (especially corticosteroids), however recognized these analyses would not be possible without access to individual participant data. To this last point, the panel recognized that usual care is likely variable between centres, regions and evolved over time. However, given all of the data come from RCTs, use of these co-interventions that comprise usual care should be balanced between study patients randomized to either the intervention or usual care arms.

Following the panel's request, the NMA team performed subgroup analyses in order to assess for effect modification which, if present, could mandate distinct recommendations by subgroups. From the data available from the included trials, subgroup analysis was only possible for severity of illness and the outcome of mortality. This subgroup analysis was performed using a random effects frequentist analysis based on the three WHO severity definitions. A post hoc Bayesian analysis was also performed, which incorporated meta-regression using study as a random effect. This latter approach has the advantage of more accurately accounting for within-study differences but can only compare two subgroups at a time. The panel used a pre-specified framework incorporating the ICEMAN tool to assess the credibility of subgroup findings (24).

#### Info Box

The recommendation concerning remdesivir was published 20 November 2020 as the [second version](#) of the WHO living guideline and in the BMJ as [Rapid Recommendations](#). No changes were made for the remdesivir recommendation in this sixth version of the guideline. Please view the section text for a summary of the evidence requested to inform the recommendation, triggered by the WHO SOLIDARITY trial.

#### Conditional recommendation against

We suggest against administering remdesivir in addition to usual care.

### Practical Info

The GDG made a conditional recommendation against using remdesivir for treatment of hospitalized patients with COVID-19. If administration of remdesivir is considered, it should be noted that its use is contraindicated in those with liver (ALT > 5 times normal at baseline) or renal (eGFR < 30 mL/minute) dysfunction. To date, it can only be administered intravenously, and it has relatively limited availability.

### Evidence To Decision

#### Benefits and harms

The GDG panel found a lack of evidence that remdesivir improved outcomes that matter to patients such as reduced mortality, need for mechanical ventilation, time to clinical improvement and others. However, the low certainty evidence for these outcomes, especially mortality, does not prove that remdesivir is ineffective; rather, there is insufficient evidence to confirm that it does improve patient-important outcomes.

There was no evidence of increased risk of SAEs from the trials. However, further pharmacovigilance is needed because SAEs are commonly underreported and rare events could be missed, even in large RCTs.

A subgroup analysis indicated that remdesivir treatment possibly increased mortality in the critically ill and possibly reduced mortality in the non-severely and severely ill. The panel judged the overall credibility of this subgroup effect (evaluated using the ICEMAN tool) to be insufficient to make subgroup recommendations. The overall low certainty evidence on the benefits and harms of remdesivir, driven by risk of bias and imprecision limitations in the included studies, also contributed to the judgment.

#### Certainty of the Evidence

Low

The evidence is based on a linked systematic review and NMA of four RCTs; pooling data from 7333 patients hospitalized with various severities of COVID-19 and variably reporting the outcomes of interest to the guideline panel (5). The panel agreed that there was low certainty in the estimates of effect for all patient-important outcomes across benefits and harms, mostly driven by risk of bias and imprecision (wide confidence intervals which do not exclude important benefit or harm). There was very low certainty evidence for viral clearance and delirium.

#### Preference and values

Substantial variability is expected or uncertain

Applying the agreed values and preferences (see Evidence section above), the GDG inferred that most patients would be

reluctant to use remdesivir given the evidence left high uncertainty regarding effects on mortality and the other prioritized outcomes. This was particularly so as any beneficial effects of remdesivir, if they do exist, are likely to be small and the possibility of important harm remains. The panel acknowledged, however, that values and preferences are likely to vary, and there will be patients and clinicians who choose to use remdesivir given the evidence has not excluded the possibility of benefit.

### Resources and other considerations

Important issues, or potential issues not investigated

A novel therapy typically requires higher certainty evidence of important benefits than currently available for remdesivir, preferably supported wherever possible by cost-effectiveness analysis. In the absence of this information, the GDG raised concerns about opportunity costs and the importance of not drawing attention and resources away from best supportive care or the use of corticosteroids in severe COVID-19. It was noted that remdesivir is administered only by the intravenous route currently, and that global availability is currently limited.

### Justification

When moving from evidence to the conditional recommendation against the use of remdesivir for patients with COVID-19, the panel emphasized the evidence of possibly no effect on mortality, need for mechanical ventilation, recovery from symptoms and other patient-important outcomes, albeit of low certainty; it also noted the anticipated variability in patient values and preferences, and other contextual factors, such as resource considerations, accessibility, feasibility and impact on health equity (see summary of these factors under Evidence to Decision).

Importantly, given the low certainty evidence for these outcomes, the panel concluded that the evidence did not prove that remdesivir has no benefit; rather, there is no evidence based on currently available data that it does improve patient-important outcomes. Especially given the costs and resource implications associated with remdesivir, but consistent with the approach that should be taken with any new drug, the panel felt the responsibility should be on demonstrating evidence of efficacy, which is not established by the currently available data. The panel noted that there was no evidence of increased risk of SAEs in patients receiving remdesivir, at least from the included trials. Further pharmacovigilance is required to confirm this, as SAEs are commonly underreported and rare events would be missed, even in large RCTs.

### Subgroup analysis

The panel carefully considered a potential subgroup effect across patients with different levels of disease severity, suggesting a possible increase in mortality in the critically ill and a possible reduction in mortality in the non-severely and severely ill. For this analysis, critical illness was defined as those requiring invasive or non-invasive ventilation, severe illness as those requiring oxygen therapy (but not meeting critical illness criteria), and non-severe as all others. Patients requiring high-flow nasal cannula represented a small proportion and were characterized as either severe (SOLIDARITY) (18) or critical (ACTT-1) (74). The analysis focused on within-study subgroup comparisons across the different severities, and therefore the SIMPLE-MODERATE trial could not be included in the subgroup analysis as it only enrolled patients with non-severe COVID-19. The panel reviewed the results of both the random effects frequentist analysis and the post hoc Bayesian analysis which incorporated meta-regression using study as a random effect.

The GDG panel judged the credibility in the subgroup analysis assessing differences in mortality by severity of illness to be insufficient to make subgroup recommendations. Important factors influencing this decision included a lack of *a priori* hypothesized direction of subgroup effect by trial investigators, little or no previously existing supportive evidence for the subgroup finding, and relatively arbitrary cut points used to examine the subgroups of interest. The overall low certainty evidence for the benefits and harms of remdesivir, driven by risk of bias and imprecision limitations, also contributed to the judgment. The panel highlighted that despite the conditional recommendation against remdesivir, they support further enrolment into RCTs evaluating remdesivir, especially to provide higher certainty of evidence for specific subgroups of patients.

The panel had *a priori* requested analyses of other important subgroups of patients including children and older persons, but there were no data to address these groups specifically. None of the included RCTs enrolled children, and although older people were included in the trials, their outcomes were not reported separately. Also, there is no pharmacokinetic or safety data on remdesivir for children. Given this, the applicability of this recommendation to children is currently uncertain.

**Clinical Question/ PICO**

**Population:** Patients with COVID-19 infection (all disease severities)  
**Intervention:** Remdesivir + usual care  
**Comparator:** Usual care

Outcome Timeframe	Study results and measurements	Comparator Standard care	Intervention Remdesivir	Certainty of the Evidence (Quality of evidence)	Plain language summary
Mortality 28 days	Odds Ratio 0.9 (CI 95% 0.7 – 1.12) Based on data from 7,333 patients in 4 studies. <sup>1</sup> (Randomized controlled)	<b>106</b> per 1000  Difference:	<b>96</b> per 1000  <b>10 fewer per 1000</b> ( CI 95% 29 fewer – 11 more )	<b>Low</b> Due to serious risk of bias and serious imprecision <sup>2</sup>	Remdesivir possibly has little or no effect on mortality.
Mechanical ventilation	Odds Ratio 0.89 (CI 95% 0.76 – 1.03) Based on data from 6,549 patients in 4 studies. 11. **Imprecision: very serious.** Wide confidence intervals.

## 7.7 Systemic corticosteroids (published 2 September 2020)

This guideline was triggered on 22 June 2020 by the publication of the preliminary report of the RECOVERY trial, which has now been published as a peer-reviewed paper (17). Corticosteroids are listed in the WHO Model List of Essential Medicines, readily available globally at a low cost, and of considerable interest to all stakeholder groups. The guideline panel was informed by combining two meta-analyses which pooled data from eight randomized trials (7184 participants) of systemic corticosteroids for COVID-19 (5)(75). The panel discussions were also informed by two other meta-analyses, which were already published and pooled data about the safety of systemic corticosteroids in distinct but relevant patient populations.

On 17 July 2020, the panel reviewed evidence from eight RCTs (7184 patients) evaluating systemic corticosteroids versus usual care

in COVID-19. RECOVERY, the largest of the seven trials, from which mortality data were available by subgroup (severe and non-severe), evaluated the effects of dexamethasone 6 mg given once daily (oral or intravenous) for up to 10 days in 6425 hospitalized patients in the United Kingdom (2104 were randomized to dexamethasone and 4321 were randomized to usual care) (17). At the time of randomization, 16% were receiving invasive mechanical ventilation or extracorporeal membrane oxygenation; 60% were receiving oxygen only (with or without non-invasive ventilation); and 24% were receiving neither.

The data from seven other smaller trials included 63 non-critically ill patients and approximately 700 critically ill patients (definitions of critical illness varied across studies). For the latter, patients were enrolled up to 9 June 2020, and approximately four-fifths were invasively mechanically ventilated; approximately half were randomized to receive corticosteroid therapy, and half randomized to no corticosteroid therapy. Corticosteroid regimens included: methylprednisolone 40 mg every 12 hours for 3 days and then 20 mg every 12 hours for 3 days (GLUCOCOVID) (76); dexamethasone 20 mg daily for 5 days followed by 10 mg daily for 5 days (two trials, DEXA-COVID19, CoDEX) (77)(78); hydrocortisone 200 mg daily for 4 to 7 days followed by 100 mg daily for 2 to 4 days and then 50 mg daily for 2 to 3 days (one trial, CAPE-COVID) (79); hydrocortisone 200 mg daily for 7 days (one trial, REMAP-CAP) (19); methylprednisolone 40 mg every 12 hours for 5 days (one trial, Steroids-SARI) (80).

Seven of the trials were conducted in individual countries (Brazil, China, Denmark, France, Spain) whilst REMAP-CAP was an international study (recruiting in 14 European countries, Australia, Canada, New Zealand, Saudi Arabia and the United Kingdom). All trials reported mortality 28 days after randomization, except for one trial at 21 days and another at 30 days. Because the mortality data from one trial (GLUCOCOVID, n=63) were not reported by subgroup, the panel reviewed only the data pertaining to the outcome of mechanical ventilation from this trial (76). An additional trial, which randomized hospitalized patients with suspected SARS-CoV-2 infection, published on 12 August 2020 (MetCOVID) (81), was included as a supplement in the PMA publication, as it was registered after the searches of trial registries were performed. The supplement showed that inclusion would not change results other than reduce inconsistency.

#### Subgroup effect for mortality

While all other trials evaluated systemic corticosteroids exclusively in critically ill patients, the RECOVERY trial enrolled hospitalized patients with COVID-19. The panel considered the results of a subgroup analysis of the RECOVERY trial suggesting that the relative effects of systemic corticosteroids varied as a function of the level of respiratory support received at randomization. On the basis of the peer-reviewed criteria for credible subgroup effects (24), the panel determined that the subgroup effect was sufficiently credible to warrant separate recommendations for severe and non-severe COVID-19.

However, acknowledging that during a pandemic, access to health care may vary considerably over time as well as between different countries, the panel decided against defining patient populations concerned by the recommendations on the basis of access to health interventions (i.e. hospitalization and respiratory support). Thus, the panel attributed the effect modification in the RECOVERY Trial to illness severity.

The panel also acknowledged the existence of variable definitions for severity and use of respiratory support interventions. The WHO clinical guidance for COVID-19 published on 27 May 2020 (version 3) defined severity of COVID-19 by clinical indicators, but modified the oxygen saturation threshold from 94% to 90%, in order to align with previous WHO guidance (12). See Section 6 for the WHO severity criteria and Infographic for three disease severity groups for which the recommendations apply in practice.

#### Info Box

The recommendations for corticosteroids were first published as [WHO living guidelines](#) 2 September 2020, and as [BMJ Rapid Recommendations](#) 5 September 2020, including links to MAGICapp. Please visit the [WHO website](#) guidelines for details (e.g. composition of the guideline panel) and view section text to understand what evidence the panel applied in creating these recommendations.

Whereas the recommendations remain unchanged, the evidence summary for corticosteroids in patients with COVID-19 was updated before this sixth iteration of this living guideline. The baseline risk estimates for mortality are now based on the WHO SOLIDARITY trial (as for other drugs in this guideline) (18) rather than the initial ISARIC cohort study (82) that likely overestimates current mortality risks at the global level. This update was also needed to inform the baseline risk for mortality in the evidence summary informing the strong recommendation for IL-6 inhibitors, in addition to standard of care for patients with severe or critical COVID-19, where corticosteroids provide a relative reduction in mortality by 21%.

## For patients with severe and critical COVID-19

### Recommended

We recommend systemic corticosteroids rather than no corticosteroids.

### Practical Info

**Route:** Systemic corticosteroids may be administered both orally and intravenously. Of note, while the bioavailability of dexamethasone is very high (that is, similar concentrations are achieved in plasma after oral and intravenous intake), critically ill patients may be unable to absorb any nutrients or medications due to intestinal dysfunction. Clinicians therefore may consider administering systemic corticosteroids intravenously rather than orally if intestinal dysfunction is suspected.

**Duration:** While more patients received corticosteroids in the form of dexamethasone 6 mg daily for up to 10 days, the total duration of regimens evaluated in the seven trials varied between 5 and 14 days, and treatment was generally discontinued at hospital discharge (that is, the duration of treatment could be less than the duration stipulated in the protocols).

**Dose:** The once daily dexamethasone formulation may increase adherence. A dose of 6 mg of dexamethasone is equivalent (in terms of glucocorticoid effect) to 150 mg of hydrocortisone (that is, 50 mg every 8 hours), 40 mg of prednisone, or 32 mg of methylprednisolone (8 mg every 6 hours or 16 mg every 12 hours).

**Monitoring:** It would be prudent to monitor glucose levels in patients with severe and critical COVID-19, regardless of whether the patient is known to have diabetes.

**Timing:** The timing of therapy from onset of symptoms was discussed by the panel. The RECOVERY investigators reported a subgroup analysis suggesting that the initiation of therapy 7 days or more after symptom onset may be more beneficial than treatment initiated within 7 days of symptom onset. A post hoc subgroup analysis within the PMA did not support this hypothesis. While some panel members believed that postponing systemic corticosteroids until after viral replication is contained by the immune system may be reasonable, many noted that, in practice, it is often impossible to ascertain symptom onset and that signs of severity often appear late (that is, denote a co-linearity between severity and timing). The panel concluded that, given the evidence, it was preferable to err on the side of administering corticosteroids when treating patients with severe or critical COVID-19 (even if within 7 days of symptoms onset) and to err on the side of not giving corticosteroids when treating patients with non-severe disease (even if after 7 days of symptoms onset).

### Evidence To Decision

#### Benefits and harms

Substantial net benefits of the recommended alternative

Panel members who voted for a conditional recommendation argued that the trials evaluating systemic corticosteroids for COVID-19 reported limited information regarding potential harm. Between the two panel meetings, indirect evidence regarding the potential harmful effects of systemic corticosteroids from studies in sepsis, ARDS and community-acquired pneumonia (CAP) was added to the summary of findings table (83)(84). While generally of low certainty, these data were reassuring and suggested that corticosteroids are not associated with an increased risk of adverse events, beyond likely increasing the incidence of hyperglycaemia (moderate certainty evidence; absolute effect estimate 46 more per 1000 patients, 95% CI: 23 more to 72 more) and hypernatraemia (moderate certainty evidence; 26 more per 1000 patients, 95% CI: 13 more to 41 more). Panel members also noted that, given the expected effect of systemic corticosteroids on mortality, most patients would not refuse this intervention to avoid adverse events believed to be markedly less important to most patients than death.

In contrast with new agents proposed for COVID-19, clinicians have a vast experience of systemic corticosteroids and the panel was reassured by their overall safety profile. Moreover, the panel was confident that clinicians using these guidelines would be aware of additional potential side-effects and contraindications to systemic corticosteroid therapy, which may vary geographically in function of endemic microbiological flora. Notwithstanding, clinicians should exercise caution in use of corticosteroids in patients with diabetes or underlying immunocompromise.

Ultimately, the panel made its recommendation on the basis of the moderate certainty evidence of a 28-day mortality reduction of 8.7% in the critically ill and 6.7% in patients with severe COVID-19 who were not critically ill, respectively. In the fifth iteration of this living guideline, mortality baseline risk estimates were updated based on the WHO SOLIDARITY

trial, considered to represent the best source of prognosis across countries facing the COVID-19 pandemic. This resulted in an overall 3.3% reduction in 28-day mortality for patients with severe or critical COVID-19, still with moderate certainty evidence and considered by the panel to represent a clear benefit to patients, with no impact on the established recommendations.

### Preference and values

No substantial variability expected

The panel took an individual patient perspective to values and preferences but, given the burden of the pandemic for health care systems globally, also placed a high value on resource allocation and equity. The benefits of corticosteroids on mortality was deemed of critical importance to patients, with little or no anticipated variability in their preference to be offered treatment if severely ill from COVID-19.

### Resources and other considerations

No important issues with the recommended alternative

#### Resource implications, feasibility, equity and human rights

In this guideline, the panel took an individual patient perspective, but also placed a high value on resource allocation. In such a perspective, attention is paid to the opportunity cost associated with the widespread provision of therapies for COVID-19. In contrast to other candidate treatments for COVID-19 that, generally, are expensive, often unlicensed, difficult to obtain and require advanced medical infrastructure, systemic corticosteroids are low cost, easy to administer, and readily available globally (85). Dexamethasone and prednisolone are among the most commonly listed medicines in national essential medicines lists; listed by 95% of countries. Dexamethasone was first listed by WHO as an essential medicine in 1977, while prednisolone was listed 2 years later (86).

Accordingly, systemic corticosteroids are among a relatively small number of interventions for COVID-19 that have the potential to reduce inequities and improve equity in health. Those considerations influenced the strength of this recommendation.

#### Acceptability

The ease of administration, the relatively short duration of a course of systemic corticosteroid therapy, and the generally benign safety profile of systemic corticosteroids for up to 7–10 days led the panel to conclude that the acceptability of this intervention was high.

## Justification

This recommendation was achieved after a vote, which concerned the strength of the recommendation in favour of systemic corticosteroids. Of the 23 voting panel members, 19 (83%) voted in favour of a strong recommendation, and 4 (17%) voted in favour of a conditional recommendation. The reasons for the four cautionary votes, which were shared by some panel members who voted in favour of a strong recommendation, are summarized below.

### Applicability

Panel members who voted for a conditional recommendation argued that many patients who were potentially eligible for the RECOVERY trial were excluded from participating in the evaluation of corticosteroids by their treating clinicians and that without detailed information on the characteristics of excluded patients, this precluded, in their opinion, a strong recommendation. Other panel members felt that such a proportion of excluded patients was the norm rather than the exception in pragmatic trials and that, while detailed information on the reasons for excluding patients were not collected, the main reasons for refusing to offer participation in the trial were likely related to safety concerns of stopping corticosteroids in patients with a clear indication for corticosteroids (confirmed as per personal communication from the RECOVERY Principal Investigator). Panel members noted that there are few absolute contraindications to a 7–10 day course of corticosteroid therapy, that recommendations are intended for the average patient population, and that it is understood that even strong recommendations should not be applied to patients in whom the intervention is contraindicated as determined by the treating clinician.

Eventually, the panel concluded that this recommendation applies to patients with severe and critical COVID-19 regardless of hospitalization status. The underlying assumption is that these patients would be treated in hospitals and receive respiratory support in the form of oxygen; non-invasive or invasive ventilation if these options were available. Following GRADE guidance, in making a strong recommendation, the panel has inferred that all or almost all fully informed patients with severe COVID-19 would choose to take systemic corticosteroids. It is understood that even in the context of a strong recommendation, the intervention may be contraindicated for certain patients. Absolute contraindications for 7–10 day courses of systemic

corticosteroid therapy are rare. In considering potential contraindications, clinicians must determine if they warrant depriving a patient of a potentially life-saving therapy.

The applicability of the recommendation is less clear for populations that were under-represented in the considered trials, such as children, patients with tuberculosis, and those who are immunocompromised. Notwithstanding, clinicians will also consider the risk of depriving these patients of potentially life-saving therapy. In contrast, the panel concluded that the recommendation should definitely be applied to certain patients who were not included in the trials, such as patients with severe and critical COVID-19 who could not be hospitalized or receive oxygen because of resource limitations.

The recommendation does not apply to the following uses of corticosteroids: transdermal or inhaled administration, high-dose or long-term regimens, or prophylaxis.

### Clinical Question/ PICO

**Population:** Patients with severe and critical COVID-19 (updated baseline mortality risk)  
**Intervention:** Steroids  
**Comparator:** Standard care

### Summary

#### Outline of the evidence on systemic corticosteroids

While six trials evaluated systemic corticosteroids exclusively in critically ill patients, the RECOVERY trial enrolled hospitalized patients with COVID-19 and reported mortality data by subgroup, whereas the smaller GLUCOCOVID trial, which also enrolled hospitalized, patients did not. The panel considered the results of a subgroup analysis of the RECOVERY trial suggesting that the relative effects of systemic corticosteroids varied as a function of the level of respiratory support received at randomization. On the basis of the peer-reviewed criteria for credible subgroup effects (24), the panel determined that the subgroup effect was sufficiently credible to warrant separate recommendations for severe and non-severe COVID-19.

*Population:* There were data from 1703 critically ill patients in seven trials. RECOVERY, the largest of the seven trials, randomized 6425 hospitalized patients in the United Kingdom (2104 were randomized to dexamethasone and 4321 were randomized to usual care). At the time of randomization, 16% were receiving invasive mechanical ventilation or extracorporeal membrane oxygenation, 60% were receiving oxygen only (with or without non-invasive ventilation), and 24% were receiving neither (17). The mortality data from six other smaller trials included approximately 700 critically ill patients (definitions of critical illness varied across studies) enrolled up to 9 June 2020, approximately four-fifths were invasively mechanically ventilated; approximately one-half were randomized to receive corticosteroid therapy, and one-half randomized to no corticosteroid therapy. For patients with severe and non-severe COVID-19, data were only available by relevant subgroup in RECOVERY (3883 patients with severe and 1535 patients with non-severe COVID-19). Because the mortality data from one trial (GLUCOCOVID, n=63) were not reported separately for severe and non-severe COVID-19 (76), the panel reviewed only the data pertaining to the outcome of mechanical ventilation from this trial.

*Interventions:* RECOVERY evaluated the effects of dexamethasone 6 mg given once daily (oral or intravenous) for up to 10 days. Other corticosteroid regimens included: dexamethasone 20 mg daily for 5 days followed by 10 mg daily for 5 days (two trials, DEXA-COVID, CoDEX); hydrocortisone 200 mg daily for 4 to 7 days followed by 100 mg daily for 2 to 4 days and then 50 mg daily for 2 to 3 days (one trial, CAPE-COVID); hydrocortisone 200 mg daily for 7 days (one trial, REMAP-CAP); methylprednisolone 40 mg every 12 hours for 5 days (one trial, Steroids-SARI); and methylprednisolone 40 mg every 12 hours for 3 days and then 20 mg every 12 hours for 3 days (one trial, GLUCOCOVID) (5). Seven of the trials were conducted in individual countries (Brazil, China, Denmark, France, Spain) whilst REMAP-CAP was an international study (recruiting in 14 European countries, Australia, Canada, New Zealand, Saudi Arabia and United Kingdom).

*Outcomes:* All trials reported mortality 28 days after randomization, except for one trial at 21 days and another at 30 days.

## For patients with non-severe COVID-19 infection (absence of criteria for severe or critical infection)

Conditional recommendation against

We suggest not to use corticosteroids.

### Practical Info

With the conditional recommendation against the use of corticosteroids in patients with non-severe COVID-19 the following practical information apply in situations where such treatment is to be considered:

**Route:** Systemic corticosteroids may be administered both orally and intravenously. Of note, while the bioavailability of dexamethasone is very high (i.e. similar concentrations are achieved in plasma after oral and intravenous intake), critically ill patients may be unable to absorb any nutrients or medications due to intestinal dysfunction. Clinicians therefore may consider administering systemic corticosteroids intravenously rather than orally if intestinal dysfunction is suspected.

**Duration:** While more patients received corticosteroids in the form of dexamethasone 6 mg daily for up to 10 days, the total duration of regimens evaluated in the seven trials varied between 5 and 14 days, and treatment was generally discontinued at hospital discharge (i.e. the duration of treatment could be less than the duration stipulated in the protocols).

**Dose:** The once daily dexamethasone formulation may increase adherence. A dose of 6 mg of dexamethasone is equivalent (in terms of glucocorticoid effect) to 150 mg of hydrocortisone (e.g. 50 mg every 8 hours), or 40 mg of prednisone, or 32 mg of methylprednisolone (e.g. 8 mg every 6 hours or 16 mg every 12 hours). It would be prudent to monitor glucose levels in patients with severe and critical COVID-19, regardless of whether the patient is known to have diabetes.

**Timing:** The timing of therapy from onset of symptoms was discussed by the panel. The RECOVERY investigators reported a subgroup analysis suggesting that the initiation of therapy 7 days or more after symptom onset may be more beneficial than treatment initiated within 7 days of treatment onset. A post hoc subgroup analysis within the PMA did not support this hypothesis. While some panel members believed that postponing systemic corticosteroids until after viral replication is contained by the immune system may be reasonable, many noted that, in practice, it is often impossible to ascertain symptom onset and that signs of severity frequently appear late (i.e. denote a co-linearity between severity and timing). The panel concluded that, given the evidence, it was preferable to err on the side of administering corticosteroids when treating patients with severe or critical COVID-19 (even if within 7 days of symptoms onset) and to err on the side of not giving corticosteroids when treating patients with non-severe disease (even if after 7 days of symptoms onset).

Other endemic infections that may worsen with corticosteroids should be considered. For example, for *Strongyloides stercoralis* hyperinfection associated with corticosteroid therapy, diagnosis or empiric treatment may be considered in endemic areas if steroids are used.

## Evidence To Decision

### Benefits and harms

The panel made its recommendation on the basis of low certainty evidence suggesting a potential increase of 3.9% in 28-day mortality among patients with COVID-19 who are not severely ill. The certainty of the evidence for this specific subgroup was downgraded due to serious imprecision (i.e. the evidence does not allow to rule out a mortality reduction) and risk of bias due to lack of blinding. In making a conditional recommendation against the indiscriminate use of systemic corticosteroids, the panel inferred that most fully informed individuals with non-severe illness would not want to receive systemic corticosteroids, but many could want to consider this intervention through shared decision-making with their treating physician (23)(12).

**Note:** WHO recommends antenatal corticosteroid therapy for pregnant women at risk of preterm birth from 24 to 34 weeks' gestation when there is no clinical evidence of maternal infection, and adequate childbirth and newborn care is available. However, in cases where the woman presents with mild or moderate COVID-19, the clinical benefits of antenatal corticosteroid might outweigh the risks of potential harm to the mother. In this situation, the balance of benefits and harms for the woman and the preterm newborn should be discussed with the woman to ensure an informed decision, as this assessment may vary depending on the woman's clinical condition, her wishes and that of her family, and available health care resources.

### Preference and values

The weak or conditional recommendation was driven by likely variation in patient values and preferences. The panel judged that most individuals with non-severe illness would decline systemic corticosteroids. However, many may want them after shared decision-making with their treating physician.

### Resources and other considerations

#### Resource implications, feasibility, equity and human rights

The panel also considered that in order to help guarantee access to systemic corticosteroids for patients with severe and critical COVID-19, it is reasonable to avoid administering this intervention to patients who, given the current evidence, would not appear to derive any benefit from this intervention.

## Justification

This recommendation was achieved by consensus.

## Applicability

This recommendation applies to patients with non-severe disease regardless of their hospitalization status. The panel noted that patients with non-severe COVID-19 would not normally require acute care in hospital or respiratory support, but that in some jurisdictions, these patients may be hospitalized for isolation purposes only, in which case they should not be treated with systemic corticosteroids. The panel concluded that systemic corticosteroids should not be stopped for patients with non-severe COVID-19 who are already treated with systemic corticosteroids for other reasons (e.g. patients with chronic obstructive pulmonary disease or other chronic autoimmune diseases need not discontinue a course of systemic oral corticosteroid). If the

clinical condition of patients with non-severe COVID-19 worsens (i.e. increase in respiratory rate, signs of respiratory distress or hypoxaemia) they should receive systemic corticosteroids (see first recommendation in Section 7.6).

**Clinical Question/ PICO**

**Population:** Patients with non-severe COVID-19

Hypernatremia	Relative risk 1.64 (CI 95% 1.32 – 2.03) Based on data from 5,015 patients in 6 studies.	<b>40</b> per 1000  Difference:	<b>66</b> per 1000  <b>26 more per 1000</b> ( CI 95% 13 more – 41 more )	<b>Moderate</b> Due to serious indirectness <sup>8</sup>	Corticosteroids probably increase the risk of hypernatremia.
Neuromuscular weakness	Relative risk 1.09 (CI 95% 0.86 – 1.39) Based on data from 6,358 patients in 8 studies.	<b>69</b> per 1000  Difference:	<b>75</b> per 1000  <b>6 more per 1000</b> ( CI 95% 10 fewer – 27 more )	<b>Low</b> Due to serious indirectness and serious imprecision <sup>9</sup>	Corticosteroids may not increase the risk of neuromuscular weakness.
Neuropsychiatric effects	Relative risk 0.81 (CI 95% 0.41 – 1.63) Based on data from 1,813 patients in 7 studies.	<b>35</b> per 1000  Difference:	<b>28</b> per 1000  <b>7 fewer per 1000</b> ( CI 95% 21 fewer – 22 more )	<b>Low</b> Due to serious indirectness and serious imprecision <sup>10</sup>	Corticosteroids may not increase the risk of neuropsychiatric effects.
Duration of hospitalization	Measured by: days Lower better Based on data from: 6,425 patients in 1 studies. (Randomized controlled)	<b>13</b> days	<b>12</b> days	<b>Low</b> Due to serious risk of bias and serious imprecision <sup>11</sup>	Steroids may result in an important reduction in the duration of hospitalizations

1. Systematic review [5] . **Baseline/comparator:** Primary study[18]. We derived baseline risk for mortality and mechanical ventilation from the control arm of the WHO SOLIDARITY trial.
2. **Risk of Bias: serious.** lack of blinding. **Imprecision: serious.**
3. **Risk of Bias: serious.** lack of blinding.
4. Systematic review. **Baseline/comparator:** Control arm of reference used for intervention. **Supporting references:** [5],
5. **Indirectness: serious. Imprecision: serious.**
6. **Indirectness: serious. Imprecision: serious.**
7. **Indirectness: serious.**
8. **Indirectness: serious.**
9. **Indirectness: serious. Imprecision: serious.**
10. **Indirectness: serious. Imprecision: serious.**
11. **Risk of Bias: serious.** lack of blinding. **Imprecision: serious.** confidence interval includes no benefit.

## 8. Uncertainties, emerging evidence and future research

The guideline recommendations for COVID-19 therapeutics demonstrate remaining uncertainties concerning treatment effects for all outcomes of importance to patients. There is also a need for better evidence on prognosis and values and preferences of patients with COVID-19 infection. Here we outline key uncertainties for casirivimab and imdevimab identified by the GDG, adding to those for ivermectin, corticosteroids, remdesivir, hydroxychloroquine, lopinavir/ritonavir and IL-6 inhibitors in previous versions of the living guideline. These uncertainties may inform future research, i.e. the production of higher certainty and more relevant evidence to inform policy and practice. We also outline emerging evidence in the rapidly changing landscape of trials for COVID-19.

### Ongoing uncertainties and opportunities for future research

#### *Casirivimab and imdevimab*

- accurate clinical prediction guides to establish individual patient risk of hospitalization in patients presenting with non-severe COVID-19 in order to best identify patients that would most benefit from this intervention;
- dosing and administration routes in non-severe and severe/critical COVID-19 patients;
- safety and efficacy in children and pregnant women.

*IL-6 receptor blockers* (despite the strong recommendation, there are a number of uncertainties that persist):

- long-term mortality and functional outcomes in COVID-19 survivors;
- safety data in terms of nosocomial infections;
- data in children, pregnant patients and those that are already immunocompromised;
- patients with non-severe COVID-19;
- immunity and the risk of a subsequent infection, which may impact the risk of death after 28 days;
- outcomes by different IL-6 receptor blocker dosing and optimal timing of drug initiation.

#### *Ivermectin*

Given the very low certainty in estimates for most critical outcomes of interest, the GDG felt that further high-quality clinical trials examining this drug would be essential before any recommendation for use as part of clinical care. This includes further RCTs examining both inpatients and outpatients and those with varying disease severities and using different ivermectin dosing regimens. The focus of these studies should be on outcomes important to patients such as mortality, quality of life, need for hospitalization, need for invasive mechanical ventilation and time to clinical or symptom improvement. Also, a better characterization of potential harms with ivermectin in patients with COVID-19 would be important.

#### *Hydroxychloroquine*

Although some uncertainty remains, the GDG panel felt that further research was unlikely to uncover a subgroup of patients that would benefit from hydroxychloroquine on the most important outcomes (mortality, mechanical ventilation) given the consistent results in trials across disease severity and location.

#### *Lopinavir/ritonavir*

Although some uncertainty remains, the GDG panel felt that further research was unlikely to uncover a subgroup of patients that would benefit from hydroxychloroquine on the most important outcomes (mortality, mechanical ventilation) given the consistent results in trials across disease severity and location.

#### *Remdesivir and effects on:*

- critical outcomes of interest, particularly those that impact resource allocation, such as the need for mechanical ventilation, duration of mechanical ventilation and duration of hospitalization;
- specific subgroups, such as different severities of illness, different time (days) since onset of illness, children and older adults, pregnant women, and duration of therapy;
- long-term outcomes such as mortality at extended endpoints or long-term quality of life;
- long-term safety and rare but important side-effects;
- patient-reported outcomes such as symptom burden;
- outcomes, when used in combination with other agents, such as, but not limited to, corticosteroids;
- impact on viral shedding, viral clearance, patient infectivity.

#### *Corticosteroids and effects on:*

- long-term mortality and functional outcomes in COVID-19 survivors;
- patients with non-severe COVID-19 (i.e. pneumonia without hypoxaemia);
- outcomes, when used in combination with additional therapies for COVID-19, such as novel immunomodulators. It will become increasingly important to ascertain how these interact with systemic corticosteroids. All investigational therapies for severe and critical COVID-19 (including remdesivir) should be compared with systemic corticosteroids or evaluated in combination with systemic corticosteroids vs systemic corticosteroids alone;
- immunity and the risk of a subsequent infection, which may impact the risk of death after 28 days;
- outcomes, by different steroid preparation, dosing and optimal timing of drug initiation.

### Emerging evidence

The unprecedented volume of planned and ongoing studies for COVID-19 interventions – over 4200 RCTs as of 1 September 2021 – implies that more reliable and relevant evidence will emerge to inform policy and practice (16). An overview of registered and ongoing trials for COVID-19 therapeutics and prophylaxis is available from the [Infectious Diseases Data Observatory](#), through their living systematic review of COVID-19 clinical trial registrations (16), the WHO website and other repositories, such as the [COVID-NMA initiative](#).

Whereas most of these studies are small and of variable methodological quality, a number of large, international platform trials (e.g. RECOVERY, SOLIDARITY and DISCOVERY) are better equipped to provide robust evidence for a number of potential treatment options (17)(18)(19)(20). Such trials can also adapt their design, recruitment strategies and selection of interventions based on new insights, exemplified by the uncertainties outlined above.

## 9. Authorship, contributions, acknowledgements

### Authorship, contributions, acknowledgements

WHO would like to thank the collaborative efforts of all those involved to make this process rapid, efficient, trustworthy and transparent, including in-kind support from the Magic Evidence Ecosystem Foundation (MAGIC) and their partner, the BMJ, to develop and disseminate this living guidance for COVID-19 drug treatments, based on a living systematic review and network meta-analysis from investigators at McMaster University, Canada (5).

### WHO Therapeutics Steering Committee

The committee includes representatives from various WHO departments at headquarters and the regions and has been approved by the WHO Director of the Country Readiness Department, and the WHO Chief Scientist. The WHO Secretariat meets on a regular basis to discuss when to trigger guideline updates based on evidence updates from the WHO rapid review team, and other sources of evidence and selects the members of the **Guideline Development Group (GDG)** for living guidance.

Janet V Diaz (Lead, Clinical Team for COVID-19 Response, Health Emergencies Programme, Geneva); John Appiah (Lead, Case Management, WHO Regional Office for Africa); Lisa Askie (Quality Assurance of Norms and Standards Department); Silvia Bertagnolio (Communicable and Noncommunicable Diseases Division/Clinical Team for COVID-19 Response); Sophie Harriet Dennis (Infection Prevention and Control and Clinical Management); Nathan Ford (Department of HIV/AIDS and Global Hepatitis Programme); Chiori Kodama (WHO Regional Office for the Eastern Mediterranean); Marta Lado Castro-Rial (Clinical Team for COVID-19 Response, Health Emergencies Programme, Geneva); Lorenzo Moja (Health Products Policy and Standards Department); Olufemi Oladapo (Sexual and Reproductive Health and Research Department); Dina Pfeifer (WHO Regional Office for Europe/Health Emergencies Programme); Jacobus Preller (Clinical Team for COVID-19 Response, Health Emergencies Programme, Geneva); Pryanka Relan (Clinical Team for COVID-19 Response, Health Emergencies Programme, Geneva); Ludovic Reveiz (Evidence and Intelligence for Action in Health Department, Incident Management Systems for COVID-19, Pan American Health Organization); Vaseeharan Sathiyamoorthy (Research for Health, Science Division); Archana Seahwag (Clinical Team for COVID-19 Response, Health Emergencies Programme, Geneva); Anthony Solomon (Neglected Tropical Diseases); Juan Soriano Ortiz (Clinical Team for COVID-19 Response, Health Emergencies Programme, Geneva); Pushpa Wijesinghe (Lead, Case Management, Regional Office for South-East Asia). Supporting project officer: Anne Colin (Clinical Team for COVID-19 Response, Health Emergencies Programme, Geneva).

The WHO Therapeutics Steering Committee is fully responsible for decisions about guidance production and convening the GDG.

We would like to acknowledge the **Guidance Support Collaboration Committee** which provided the coordination between WHO and MAGIC to allow the rapid development of the WHO guidance and its dissemination: Thomas Agoritsas (MAGIC, University Hospitals of Geneva); Janet Diaz (World Health Organization), Fiona Godlee (British Medical Journal); Gordon Guyatt (McMaster University, Canada); Navjoyt Ladher (British Medical Journal); François Lamontagne (Université de Sherbrooke, Canada); Srinivas Murthy (University of British Columbia, Canada); Bram Rochweg (McMaster University, Canada); Archana Seahwag (World Health Organization); Per Olav Vandvik (MAGIC, University of Oslo).

### Guideline Development Group (GDG) for V6 of guideline. For list of GDG members of previous recommendations, see [here](#)

Wagdy Amin (Ministry of Health and Population, Egypt); Frederique Bausch (Geneva University Hospital, Switzerland); Erlina Burhan (Infection Division Department of Pulmonology and Respiratory Medicine Faculty of Medicine Universitas Indonesia); Carolyn S Calfee (University of California, San Francisco); Maurizio Cecconi (Humanitas Research Hospital Milan, Italy); Duncan Chanda (Adult Infectious Disease Centre, University Teaching Hospital, Lusaka, Zambia); Vu Quoc Dat (Department of Infectious Diseases, Hanoi Medical University, Hanoi, Viet Nam); Bin Du (Peking Union Medical College Hospital); Heike Geduld (Emergency Medicine, Stellenbosch University, South Africa); Patrick Gee (patient panel member, United States of America); Nerina Harley (Royal Melbourne Hospital and Epworth Healthcare, Melbourne, Australia); Madiha Hashmi (Ziauddin University, Karachi, Pakistan); Manai Hela (Emergency Medical Service Tunis, Tunisia); Beverley Hunt (Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom); Sushil Kumar Kabra (All India Institute of Medical Sciences, New Delhi, India); Seema Kanda (patient panel member, Ontario, Canada); Leticia Kawano-Dourado (Research Institute, Hospital do Coração, São Paulo, Brazil); Yae-Jean Kim (Sungkyunkwan University School of Medicine, Samsung Medical Center, Seoul, Republic of Korea); Niranjana Kisson (Department of Paediatrics and Emergency Medicine, University of British Columbia, Vancouver, Canada); Arthur Kwizera (Makerere College of Health Sciences, Kampala, Uganda); Yee Sin Leo (National Centre for Infectious Diseases, Singapore); Imelda Mahaka (patient panel member, Pangaea Harare, Zimbabwe); Greta Mino (Alcivar Hospital in Guayaquil, Ecuador); Emmanuel Nsutebu (Sheikh Shakhbout Medical City, Abu Dhabi); Natalia Pshenichnaya (Central Research Institute of Epidemiology of Rospotrebnadzor, Moscow, Russian Federation); Nida Qadir (Pulmonary and Critical Care Medicine, David Geffen School of Medicine, University of California, Los Angeles, United States of America); Saniya Sabzwari (Aga Khan University, Karachi, Pakistan); Krishna Sanjeev (St George's, University of London, United Kingdom); Rohit Sarin (National Institute of Tuberculosis and Respiratory Diseases, New Delhi, India); Yinzhong Shen (Shanghai Public Health Clinical Center, Fudan University, Shanghai, China); Shalini Sri Ranganathan (University of Colombo, Sri Lanka); Miriam Stegeman (Charité - Universitätsmedizin Berlin, Germany); Ann De Sutter (University of Gent, Belgium); Sebastian Ugarte (Faculty of Medicine Andres Bello University, Indisa Clinic, Santiago, Chile);

Sridhar Venkatapuram (King's College, London); Dubula Vuyiseka (patient panel member, University of Stellenbosch, South Africa); Ananda Wijewickrama (Ministry of Health, Sri Lanka).

#### Methods chairs

Gordon Guyatt (casirivimab and imdevimab), Bram Rochweg (IL-6 receptor blockers, ivermectin, remdesivir and lopinavir-ritonavir), Reed Siemieniuk (hydroxychloroquine), Francois Lamontagne (corticosteroids).

#### Clinical chairs

Michael Jacobs (casirivimab and imdevimab, IL-6 receptor blockers, ivermectin, remdesivir, hydroxychloroquine, and lopinavir-ritonavir), Yee-Sin Leo (corticosteroids).

#### Methods resource persons

Arnav Agarwal (University of Toronto, Canada); Thomas Agoritsas (University Hospitals of Geneva, Switzerland); Romina Brignardello-Petersen (McMaster University, Canada); Gordon H Guyatt (McMaster University, Canada); George Tomlinson (Department of Medicine, University Health Network, Toronto, Canada); Per Olav Vandvik (MAGIC, University of Oslo Norway), Linan Zeng (West China Second University Hospital, Sichuan University, Chengdu, China; McMaster University, Canada).

#### Living systematic review/NMA team

Arnav Agarwal (University of Toronto, Canada); Thomas Agoritsas (MAGIC, University Hospitals of Geneva); Jessica J Bartoszko (McMaster University, Canada); Romina Brignardello-Petersen; Derek K Chu (McMaster University, Canada); Rachel Couban (McMaster University, Canada); Andrea Darzi (McMaster University, Canada); Tahira Devji (McMaster University, Canada); Bo Fang (Chongqing Medical University, Chongqing, China); Carmen Fang (William Osler Health Network, Toronto, Canada); Signe Agnes Flottorp (Institute of Health and Society, University of Oslo, Norway); Farid Foroutan (McMaster University, Canada); Long Ge (School of Public Health, Lanzhou University, Gansu, China); Gordon H Guyatt (McMaster University, Canada); Mi Ah Han (College of Medicine, Chosun University, Gwangju, Republic of Korea); Diane Heels-Ansell (McMaster University, Canada); Kimia Honarmand (Department of Medicine, Western University, London, Canada); Liangying Hou (School of Public Health, Lanzhou University, Gansu, China); Xiaorong Hou (Chongqing Medical University, Chongqing, China); Quazi Ibrahim (McMaster University, Canada); Ariel Izcovich (Servicio de Clinica Médica del Hospital Alemán, Buenos Aires, Argentina); Elena Kum (McMaster University, Canada); Francois Lamontagne; Qin Liu (School of Public Health and Management, Chongqing Medical University, Chongqing, China); Mark Loeb (McMaster University, Canada); Maura Marcucci (McMaster University, Canada); Shelley L McLeod (Schwartz/Reisman Emergency Medicine Institute, Sinai Health, Toronto, Canada); Sharhzad Motaghi, (McMaster University, Canada); Srinivas Murthy; Reem A Mustafa (McMaster University, Canada); John D Neary (McMaster University, Canada); Hector Pardo-Hernandez (Iberoamerican Cochrane Centre, Sant Pau Biomedical Research Institute [IIB Sant Pau], Barcelona, Spain); Anila Qasim (McMaster University, Canada); Gabriel Rada (Epistemonikos Foundation, Santiago, Chile); Irbaz Bin Riaz (Hematology and Oncology, Mayo Clinic Rochester, Rochester, United States of America); Bram Rochweg (McMaster University, Canada); Behnam Sadeghirad (McMaster University, Canada); Nigar Sekercioglu (McMaster University, Canada); Lulu Sheng (School of Public Health and Management, Chongqing Medical University, Chongqing, China); Reed AC Siemieniuk; Ashwini Sreekanta (McMaster University, Canada); Charlotte Switzer (McMaster University, Canada); Britta Tendal (School of Public Health and Preventive Medicine, Monash University, Melbourne, Australia); Lehana Thabane (McMaster University, Canada); George Tomlinson; Tari Turner (School of Public Health and Preventive Medicine, Monash University, Melbourne, Australia); Per Olav Vandvik (MAGIC, University of Oslo, Norway); Robin WM Vernooij (Department of Nephrology and Hypertension, University Medical Center Utrecht, Netherlands); Andrés Viteri-García (Epistemonikos Foundation, Santiago, Chile); Ying Wang (McMaster University, Canada); Liang Yao (McMaster University, Canada); Zhikang Ye (McMaster University, Canada); Dena Zeraatkar (McMaster University, Canada) (5).

**Special thanks to WHO Rapid Evidence Appraisal for COVID-19 Therapies (REACT) Working Group** for their publication: Association of Administration of Interleukin-6 Antagonists with Mortality and Other Outcomes Among Hospitalized Patients With COVID-19: A Prospective Meta-Analysis (40).
